Verbal repertoires. The totality of dialectal and superposed variants regularly employed within a community make up the *verbal repertoire* of that community. Whereas the bounds of a language, as this term is ordinarily understood, may or may not coincide with that of a social group, verbal repertoires are always specific to particular populations. As an analytical concept the verbal repertoire allows us to establish direct relationships between its constituents and the socioeconomic complexity of the community.

We measure this relationship in terms of two concepts: *linguistic range* and *degree of compartmentalization*. Linguistic range refers to internal language distance between constituent varieties, that is, the total amount of purely linguistic differentiation that exists in a community, thus distinguishing among multilingual, multidialectal, and homogeneous communities. Compartmentalization refers to the sharpness with which varieties are set off from each other, either along the superposed or the dialectal dimension. We speak of compartmentalized repertoires, therefore, when

several languages are spoken without their mixing, when dialects are set off from each other by sharp isogloss bundles, or when special parlanges are sharply distinct from other forms of speech. We speak of fluid repertoires, on the other hand, when transitions between adjoining vernaculars are gradual or when one speech style merges into another in such a way that it is difficult to draw clear borderlines.

Initially, the linguistic range of a repertoire is a function of the languages and special parlanges employed before contact. But given a certain period of contact, linguistic range becomes dependent upon the amount of internal interaction. The greater the frequency of internal interaction, the greater the tendency for innovations arising in one part of the speech community to diffuse throughout it. Thus, where the flow of communication is dominated by a single all-important center—for example, as Paris dominates central France—linguistic range is relatively small. Political fragmentation, on the other hand, is associated with diversity of languages or of dialects, as in southern Germany, long dominated by many small, semi-independent principalities.

Over-all frequency in interaction is not, however, the only determinant of uniformity. In highly stratified societies speakers of minority languages or dialects typically live side by side, trading, exchanging services, and often maintaining regular social contact as employer and employee or master and servant. Yet despite this contact, they tend to preserve their own languages, suggesting the existence of social norms that set limits to freedom of intercommunication. Compartmentalization reflects such social norms. The exact nature of these sociolinguistic barriers is not yet clearly understood, although some recent literature suggests new avenues for investigation.

We find, for example, that separate languages maintain themselves most readily in closed tribal systems, in which kinship dominates all activities. Linguistically distinct special parlanges, on the other hand, appear most fully developed in highly stratified societies, where the division of labor is maintained by rigidly defined barriers of ascribed status. When social change causes the breakdown of traditional social structures and the formation of new ties, as in urbanization and colonialization, linguistic barriers between varieties also break down. Rapidly changing societies typically show either gradual transition between speech styles or, if the community is bilingual, a range of intermediate varieties bridging the transitions between extremes.

LINTON, RALPH

Ralph Linton (1893-1953), American cultural anthropologist, was one of the major contributors to the reconstruction of anthropology during the second quarter of the twentieth century. Trained in the traditions of the North American "historical

school" of anthropology, Linton remained loyal throughout his career to the broad interests and general principles established by Franz Boas and other American anthropologists. But with the publication in 1936 of *The Study of Man*, which was quickly recognized by social scientists all over the world as a pioneering study of human behavior, he embarked on a series of creative and stimulating studies which provided new conceptions of social structure and cultural organization. He related these conceptions in a clear if somewhat simple manner to the biological individual and his personality and utilized them in his analyses of the processes of cultural change.

Linton belonged to the "third generation" of American academic anthropologists, succeeding such second-generation students of Putnam and Boas as Wissler, Dixon, Kroeber, Goldenweiser, Lowie, Sapir, and Radin. These academicians, together with a number of outstanding journeymen and masters involved more in field research than in teaching, had created a distinctive variety of anthropology. Like Tylor in England, they had a holistic approach to human studies which is still, thanks in part to Linton, a mark of American anthropology.

In the Americas much more than in Europe almost all anthropological study and training had been nurtured by experience in the field and disciplined by the empiricism required by field work on specific problems treating the temporal and spatial dimensions of culture. In dealing with the elements of local aboriginal development or culture history, most American anthropologists insisted that the combined skills of all the arts and sciences, as they may be relevant to the study of man, should be brought to bear on the task at hand. [See ETHNOGRAPHY.]

Linton's own teaching, writing, and research encompassed human biology, archeology, ethnography, ethnology, folklore, and regional and global cultural history. He contributed to all of these classical subfields of his discipline, although less significantly to physical anthropology, archeology, and folklore than to the others. He neglected technical developments in linguistics and approached the field with respectful diffidence, but he urged his students to become familiar with it, since he felt that it was the most scientific of the social disciplines. He did not emphasize statistical studies, nor did he use specialized mathematical methods in cultural or psychological anthropology, although he recognized these as legitimate activities. It was not any aversion to formalism or structuralism as such that made Linton shy away from these aspects of anthropology, for his approach to culture and to

personality studies was essentially formalistic and structural.

Like many other American anthropologists who began as archeologists, Linton's professional career started with a focus on artifacts. As a boy he had systematically collected arrowheads, and his interests in artifacts continued throughout his life as he privately gathered outstanding examples of African textiles and masks, Peruvian ceramics, and Oceanic sculpture. Linton's eidetic memory and extraordinary capacity for visual imagery enabled him to identify and compare artifacts from all over the world; and he could retrieve data from the masses of material he had read, explaining that often he could simply "turn the pages" in his mind and reread them.

Linton did his undergraduate work at Swarthmore College, a liberal institution to which his Philadelphia Quaker background led him. The college offered no studies in anthropology, but Linton was a good student in the natural sciences and an omnivorous reader in history and literature, and he decided, as he later recalled, that anthropology provided the most promising opportunity for a synthesis of varied fields. In 1912 and 1913 Linton joined field expeditions working in the American southwest and in Guatemala; and in the summer of 1915, after receiving his B.A., he discovered in New Jersey a prehistoric site of controversial importance, which he described in his first professional publications in the two following years. His graduate training at the University of Pennsylvania, where he obtained an M.A. in 1916, at Columbia University, and finally at Harvard University, where he completed his Ph.D. in 1925, was heavily weighted on the side of archeology and physical anthropology. Linton had two more summers of archeological experience in the southwestern United States, one in 1916 for the American Museum of Natural History and another in 1919 following his return from army service in France. He embarked in 1920 on his doctoral research on the archeology of the Marquesas Islands.

Linton's two years in Polynesia proved a turning point in his career, for he found work with living Marquesans more rewarding than his study of the meager remains of their ancestors. His concern for archeological problems continued—he was later active in excavations in Ohio and Wisconsin, and his posthumously published reconstruction of global cultural history demonstrates the mastery he always maintained over the data of world prehistory (see 1955)—but from the early 1920s on, his primary interest was the study of contemporary peoples.

On his return from Polynesia in 1922 he joined

the staff of the Field Museum of Natural History in Chicago, working on Oceanic and American Indian materials and conducting a one-man ethnographic expedition to Madagascar and adjacent parts of east Africa from 1925 to 1927. The publications he prepared during his years as a curator in Chicago indicate that for him the main task of ethnology was not far removed from that of archeology—the reconstruction of human history through careful descriptive studies of the development and distribution of cultural traits. Thus, when Linton began his own teaching career, accepting the first tenure position in anthropology at the University of Wisconsin, in 1928, he had moved little beyond the range of interests which had preoccupied the two preceding generations of American anthropologists.

His early years in the department of sociology at Wisconsin (soon the department of sociology and anthropology) marked the major turning point in Linton's intellectual and professional progress. He suddenly acquired wide interests in the many dimensions of human behavior. The competent fieldworker, museum archeologist, and ethnologist became in a few years a leading American social scientist.

Linton was an excellent lecturer and teacher. Almost as soon as he arrived at Wisconsin he acquired a following of young scholars who had done their undergraduate work at the university; John Dollard, J. P. Gillin, E. A. Hoebel, Clyde Kluckhohn, Lauriston Sharp, and Sol Tax were among them. Although none of these completed his graduate training under Linton, they were nonetheless widely identified with him. A number of colleagues had a marked influence on Linton's thinking during his early years at Wisconsin. He said that Kimball Young, the social psychologist, had perhaps helped him most in developing his view of social organization and its relation to individual personality formation; but he also acknowledged his debt to other members of the department, as well as to the psychologists Clark Hull and Harry Harlow, the geneticist Michael F. Guyer, the political scientist John Gauss, and the ethicists F. C. Sharp and Eliseo Vivas. Students in the university's newly established Experimental College, while dealing with the large problems of order and change in the civilizations of classical Greece and modern America, were reading a wide range of materials bearing on cultural anthropology, and Linton participated in sessions on the nature and organization of culture and civilization that were unlike most anthropology courses of the day.

For a few years during the early 1930s A. R. Radcliffe-Brown, then a leader of the British

functionalist school of social anthropology, taught at the University of Chicago, where Linton maintained informal connections. At that time Radcliffe-Brown was claiming in a somewhat doctrinaire manner that history is irrelevant to the real task of social anthropology, which is to study societies synchronically and induce general sociological laws through a comparison of the forms and functions of the social organizations of particular living societies. To Linton, the rejection of history, however fragmentary and insecure our knowledge of it may be, was anathema. However, his own field work had convinced him that the task of determining the functions of segments or complexes of cultural behavior as well as the functional interdependence of parts within the totality of a culture is a legitimate and essential one (1933). Furthermore, Linton himself was seeking regularities and general principles in the varied array of cultural experience in different times and places. Thus, in their intellectual objectives the two scholars were close together, however they differed as to means. Linton's correspondence of the period indicates that he deplored Radcliffe-Brown's considerable influence on younger members of the profession as a threat to the larger traditional concerns of American anthropology and one which he felt personally obligated to combat. However, the discussions which took place between the two men sharpened Linton's perceptions of Radcliffe-Brown's own special field of social structure and led him to argue for improved functional analyses which would take into account historical factors. Eventually this point of view largely prevailed on both sides of the Atlantic.

In the 1930s the new developments in psychiatry, psychology, European sociology, and functionalism began to influence American anthropologists, particularly Sapir, Benedict, Margaret Mead, and Hallowell. Physical anthropology and archeology, which had links to the natural sciences, and linguistics were beginning to develop rapidly and even in America were showing a strong tendency to go their separate ways. However, Linton's eclectic and wide-ranging approach to the study of man and his behavior enabled him to bring together some of these radically diverging historical, sociological, psychological, and biological interests which were dividing the anthropologists. His contributions to unity were open-ended; he found it unnecessary to impose any single closed, elaborate, or wholly consistent theoretical system on the social sciences.

Concept of culture. The work which Linton always considered his major contribution to anthropology, *The Study of Man* (1936), was written

in a simple but lively style which attracted layman and scientist alike. While intended as a text, it lacked the apparatus of a school book, containing only two footnotes and an almost irrelevant bibliography prepared hastily by a student. Except for the absence of sections on religion and the arts (originally intended for inclusion but not completed), the work was representative of the main areas of Linton's interests and foreshadowed the main thrusts of his later thinking.

Following a short opening section on human origins and the biological and primate backgrounds to cultural behavior, later elaborated in *The Tree of Culture* (1955), Linton turned directly to the individual as he interacts in defined social contexts with other individuals: the network of learned and shared behavior of individuals—their culture—creates or maintains a community or society. He conceived of culture as both overt, or open to observation, and covert, with an inferred content of meanings, emotions, values, attitudes, “and so on.”

While Linton could speak of “the mind” without blushing, he failed to deal effectively with cognition and other epistemological problems, seeing the mind as a wholly internal private sense organ rather than as a process or a product of the transaction of social business between the external and the inner worlds. As he later became involved more explicitly with psychoanalytic theory, Linton increasingly dealt with the category of covert behavior as though emotion is the prime ingredient and almost the sole source of data for the inner workings of the human personality, thus almost entirely neglecting cognitive processes.

Status and role. Linton developed his concepts of “status” and “role” to deal with the discrete elements as well as the integrated aspects of society. By status he meant the place of an individual in society, defining it as a collection of rights and duties; by role he meant the dynamic aspect of behavior in a status, the putting into action of rights and duties (1936, pp. 113–114). Statuses and roles may be universal or specialized, depending on whether they are shared by all members of a society or only by a segment of the society. Roles appropriate to a given status are not necessarily performed in the same way by all those members of the society in that status, nor are they even performed identically by the same individual at different times. There may be recognized alternative ways of achieving particular customary goals: such alternative roles may arise within the society or they may be imported from without. Behavior in a role, according to Linton, is simply behavior appropriate to a particular recognized status.

Statuses or positions are, in Linton's view, either

ascribed to the individual—that is, assigned at birth, on the basis of sex, caste, or other fixed characteristics—or they are achieved by the individual by virtue of his own effort. Roles also are of two kinds: “actual” roles—the way roles are in fact performed; and “ideal” roles—the normative patterns that serve as models for actual role performance. The total set of ideal roles constituted for Linton a social system. With this conception of roles, including child roles and those acquired as an adult, Linton laid the foundation of a theory of behavior that could bridge the gap between the individual and the cultural system.

Personality and culture. Instead of systematically refining these ideas or attempting a synthesis along the lines developed in social psychology, Linton pursued his interest in the nature of the relation between the individual personality and society. In 1937 he went to Columbia University and began there a period of collaboration in seminars and publications with Abram Kardiner, a psychoanalyst. Their views were published, with documentary ethnographic analyses, in *The Individual and His Society* (Kardiner 1939) and *The Psychological Frontiers of Society* (Kardiner 1945). From this work emerged the concept of basic personality structure, or modal personality type—

... that personality configuration which is shared by the bulk of the society's members as a result of the early experiences which they have in common. It does not correspond to the total personality of the individual, but rather to the projective systems or, in different phraseology, the value-attitude systems which are basic to the individual's personality configuration. Thus the same basic personality types may be reflected in many different forms of behavior and may enter into many different total personality configurations. (Kardiner 1945, p. viii)

Somewhat disenchanted with the psychoanalytic approach, Linton expounded his own views in *The Cultural Background of Personality* (1945a), showing how each individual's experiences in a society—his performance of a particular set of more or less standardized cultural roles—produce what Linton then called the “status personality.” The common elements of the status personalities found in a group of persons may be considered the basic personality type for a culture. Linton dealt with problems of deviation from type in a posthumously published volume, *Culture and Mental Disorders* (1956). While some anthropologists before Linton had been concerned with the individual, it was Linton's structural approach through status and role that did much to open the way for a retreat from the prevalent extreme reification of culture. [See AGE DIFFERENTIATION; CULTURE AND PERSON-

ALITY; INDIVIDUAL DIFFERENCES, *article on SEX DIFFERENCES*; NATIONAL CHARACTER; STATUS, SOCIAL.]

Hierarchy of interests. Related to Linton's concern with culture and personality and the character structure of ethnic groups was his work on the cultural interests, orientations, and values of groups. He was dissatisfied with Benedict's conclusion, in her popular *Patterns of Culture* (1934), that the total behavior of a society or of most of its members may express, through a dominant cultural pattern or configuration, a single mode of feeling or world view heavily biased in a particular direction. While agreeing that cultures are configurations, Linton suggested that any culture exhibits a whole range of patterned "interests," each of which has a "rating" reflecting its importance relative to other interests of the group. Only empirical investigation can reveal which particular interest or set of interests dominates the others in a given period and so provides the culture with an over-all orientation (1936, chapters 20, 24, 25). Morris Opler and others later refined this idea through the concept of "themes."

In his later years, and particularly after he accepted a Sterling professorship at Yale University in 1946, Linton returned to a problem which had engaged him at Wisconsin, the question of cultural relativity and the possibility that all cultures may exhibit certain universal ethical or other values. He asserted that there are common denominators of behavior among all cultures and that these support common values which then must be described at a rather abstract level (1952; 1954).

Cultural change. Linton's preoccupation with problems of culture history and culture change persisted from his first experience as an archeologist through his entire career; it even motivated his interest in the balanced relationships between the maturing individual and the changing culture in which he participates. Yet in his search for explanations of cultural change and transfer, Linton did not explore these relationships fully or systematically; rather, to explain the effective elements in change, acculturation, and social movements, he pointed to such general factors as the utility of the new, the compatibility of the new with the old, and the prestige of the innovator (1940). [See CULTURE, *article on CULTURE CHANGE*.]

Linton believed profoundly that the social sciences could become rigorous sciences and that their findings should inform the work of those dealing with current social problems (1945b, p. xlii).

However, he was not optimistic about the immediate prospects of modern civilization. His own creative innovations were widely recognized and he received the highest academic and professional honors from colleagues both within and outside his discipline. But he felt that this recognition of his work had been won in a rare period of freedom, one which could not last and which was already threatened by the bigotries which had appeared abroad and at home in his own lifetime. Expecting a "dark age," he dedicated *The Study of Man* (1936) to "the next civilization"; and almost two decades later he concluded *The Tree of Culture* (1955) in the same vein, expressing the hope that the social sciences would use this period of unusual freedom to prepare some "solid platform from which the workers of the next civilization might go on."

LIPPMANN, WALTER

Walter Lippmann was born in 1889 in New York City. His upper-middle-class family exposed him early to art, music, and literature. He attended Harvard University, where he completed the requirements for the A.B. degree in three years. His fourth year at Harvard was spent as an assistant to the philosopher George Santayana; and he graduated formally with the celebrated class of 1910, which included many others who later became prominent in the arts, the sciences, and public affairs.

An early desire to write—he had published several pieces of social criticism in the *Harvard Monthly*—turned him to journalism as a career. His first opportunity came through Lincoln Steffens, who went to Harvard in search of “the ablest mind that could express itself in writing” to help him with a series of muckraking articles for *Everybody's Magazine*.

Lippmann's accomplishments as a writer rapidly attracted the attention of those intellectual circles which were influential in the progressive climate of the prewar years. A short and disappointing stint as secretary to the socialist mayor of a city in upstate New York was followed by a brief period of free-lance writing for several magazines. But it was an invitation from Herbert Croly to join the editorial board of a new liberal journal, the *New Republic*, that provided Lippmann with a congenial and more permanent environment for his talents. No longer a socialist, yet one of the young “movers and shakers” whose intellectual vitality made the period immediately prior to World War I a seedtime of new ideas and limitless hope for the future, Lippmann found in the pages of the *New Republic* an outlet for articles on almost any topic about which he chose to write.

The *New Republic* became increasingly identified with President Wilson's policies, and in 1917 Lippmann was appointed executive secretary of a postwar planning group, the so-called House Inquiry. The following year he received a commission as captain in military intelligence to conduct propaganda on the western front. At the end of the war he was attached to the American Commission to Negotiate the Peace. In this capacity he prepared, in collaboration with Frank Cobb, then editor of the *New York World*, an elaborate memorandum on Wilson's Fourteen Points which served the American delegation as a basis for the peace discussions.

Lippmann was disappointed at the commitments and concessions made by the United States at the Versailles Peace Conference and soon returned to

the *New Republic*. But shortly thereafter he took leave from the magazine to write *Public Opinion* and, upon finishing the book in 1922, was invited to become an editorial writer for the *World*. After Cobb's death in 1923, Lippmann was placed in charge of the paper's editorial page, and in 1929 he became its editor. Although some critics castigated his measured direction of the editorial page as evasion and pusillanimity, the *World* remained, until its end in 1931, in the forefront of those fighting against social and political injustice and for liberal reforms, both within American society and in international relations.

In 1931 Lippmann surprised many of his admirers by accepting an offer to write an independent column for the conservative and traditionally Republican *New York Herald Tribune*. He was evidently given a free hand to write as he pleased, but from 1936 on, his affiliations and connections were no longer with those individuals and groups generally called liberal or progressive. He had become, more than any other columnist or commentator, a spokesman of the American “establishment.”

Intellectual development. Lippmann's years at Harvard had a deep and lasting effect on his intellectual development. He had come in contact there with socialist ideas and, for a short time, had been active in the socialist movement. He had also met William James, whose philosophy of pragmatism provided a necessary foil for Santayana's humanist idealism. And most important, he had met the English social scientist and Fabian ideologue Graham Wallas, whose *Human Nature in Politics* (1908) gave direction to Lippmann's early writings.

The more indirect influence of Sigmund Freud was at least as important as any other for Lippmann's work on public opinion and public morality. He had read Freud while writing *A Preface to Politics* (1913), and Freud's ideas seem to have played a most important part in making Lippmann aware of the obstacles to that full rationality which he deemed the goal of intellectual effort.

Finally, one cannot ignore the intellectual impact that his colleagues on the *New Republic* probably had on Lippmann. The editors had divergent ideas which had to be related to one another in order to give the magazine a semblance of unity. There was the centralist, Hamiltonian nationalism that Croly had articulated in *The Promise of American Life* (1909); but there was also the decentralist, Jeffersonian radicalism that Walter E. Weyl, another editor, expressed in *The New Democracy* (1912). Lippmann surely learned at the *New Republic* the tolerance in the face of

conflicting ideas that he called "disinterestedness" and which he cherished so much.

Lippmann's own basic intellectual position is extremely difficult to describe, especially since, until his more advanced years, his political outlook rarely remained the same for long. The key to his successive political shifts may lie in Lippmann's statement that "every truly civilized and enlightened man is conservative and liberal and progressive" (1962, p. 11). The best we can do is to examine Lippmann's major works and to distinguish the different stages in his intellectual development.

Major works. Two of Lippmann's early books—*A Preface to Politics* (1913) and *Drift and Mastery* (1914)—testify to his shift from socialism and progressivism to pragmatic liberalism. *A Preface to Politics* is the more important work, for it also contains a protest against the empty formalism and legalism of much political discussion. Lippmann described the book as "a preliminary sketch for a theory of politics, a preface to thinking," and it is not surprising, given his training in philosophy, that he should have begun his writings on this epistemological note. The problem of how to think about things political continued to be a theme throughout his writings.

His basic premises in *A Preface to Politics* are that government is not a routine to be administered but a problem to be solved and that the desires of man, rather than artificially contrived institutional mechanisms, are the proper study of politics. Reason, he felt, must serve the dual purpose of setting direction to human wants and providing the tools for their satisfaction.

The uses of reason as a tool is the main theme of *Drift and Mastery*. Not traditional authority but the method of science must be harnessed to attain human goals. Only this method will permit different persons to agree on what the facts are and to reach the same conclusions. It alone can replace passion with intelligence. The failure of progressivism was its inability to understand the changes that the new industrialism had brought about. Science is "the culture under which people can live forward in the midst of complexity, and treat life not as something given but as something to be shaped" (1914, p. 275).

After World War I Lippmann came to doubt that it is possible, and even that it is desirable, to create a rational society. In *Liberty and the News* (1920), he still expressed a belief that democracy can function, provided the public is supplied with reliable and relevant information. Two years later, however, in *Public Opinion* (1922), he came close to questioning whether citizens can possibly make

rational, democratic decisions: the source of the difficulty in forming an intelligent public opinion is not man's irrationality but the necessity, inherent in the modern communications system, of condensing information into brief slogans. These slogans create a wall of stereotypes between the citizen and the issues to which he is expected to respond.

Lippmann's analysis of the public opinion process was remarkably advanced, considering that his contemporaries were still thinking in terms of such categories as "herd instinct" or "group mind." He recognized that both the external environment and man's own psyche are sources of errors that distort perceptions and opinions. Lippmann's use of the concept of stereotype in the analysis of public opinion was an original contribution and has remained a valuable one. Somewhat less original but very cogent was Lippmann's discussion of the role of the expert in public decision making. He did not consider the expert to be a mover and shaker in his own right; rather, he produces facts that may be helpful to those who do make decisions for the benefit of the mass. The mass, Lippmann concluded, is to all intents and purposes inarticulate—it does not decide issues; at most, it assents to or dissents from a proposition about a given issue.

While this denial of the possibility of genuine—in contrast with manipulated—democratic consensus is of course a prejudgment rather than a statement of fact, *Public Opinion* was predominantly analytical. Its sequel, *The Phantom Public* (1925), was frankly polemical. Here Lippmann asserted that the public's role in a democracy is a shadowy one, but he did not accept the conclusions of those conservative critics of democracy who celebrated the rule of an elite. However, his skepticism about the ability of the masses to decide on the merits of a question reflected his own disillusionment with the traditional theory of democracy. Unlike other critics, he became a skeptic moralist rather than an elitist. Morality is a relative, not an absolute, matter, determined at any given time by what men want rather than by what they know to be true, for "a code of the right and the wrong must wait upon a perception of the true and the false" (1925, p. 30). Since such perception is extraordinarily difficult, a code is virtually impossible to achieve.

Skeptic moralist though he had come to be, Lippmann could not accept a morality based on naked desires. Desires must be subjected to the moral test; and in the case of a humanistic morality appropriate to modern conditions, human experience rather than divine revelation must pro-

vide the criteria of good and evil. In his next major work, *A Preface to Morals* (1929), Lippmann sought to formulate a new public morality.

The moral test that Lippmann proposed for action was rationality and disinterestedness. Yet, having stated this moral imperative, he continued to doubt the multitude's ability to accept it. Statesmen and leaders would first have to re-educate the wants and desires of the many, and pending this outcome, these leaders must act on the basis of what the people will *in the end* consider good, rather than on the basis of their present desires.

A Preface to Morals in a sense reasserted Lippmann's faith in the rationality of man, tempered by psychological insight into man's volatility; it stated a belief in the possibility of responsible leadership but made the leaders subject to an ideal: and it excoriated current conditions as much as it expressed a new hope for the good society.

The appearance of the New Deal in America and of National Socialism in Germany presented a new challenge to Lippmann's thought. Initially his response to the New Deal was a favorable one, for the New Deal revived his old faith in the possibility of a rational ordering of society. In two small books, *The Method of Freedom* (1934) and *The New Imperative* (1935), his outlook was hopeful. But by 1937, in his *Inquiry Into the Principles of the Good Society*, his appraisal had changed. He identified the compensatory economy of the New Deal with the regimented economy of the totalitarian state, seeing both as evidence of the "collectivist heresy." Moreover, his old suspicion of irrational majorities was linked with a new fear of an irresponsible executive. Gradual collectivism, no less than any other collectivism, makes for arbitrary government.

True liberalism, he asserted in *The Good Society*, must insist on two social mechanisms that are threatened by the collectivist order—the free market and the law. With the market as the prime regulator of the division of labor, the state's function is limited to the administration of justice among men conducting their own affairs in terms of a common law of reciprocal rights and duties. Large public expenditures for education and public works are to be retained, as is protection against the hazards of a free economy, for liberalism is "radical in relation to the social order but conservative in relation to the division of labor in a market economy" (1937, p. 236). As to the role of the executive, society is so pluralistic and diversified that the statesman can only hope to reconcile social conflicts, but he cannot treat society as if it were an organization.

With the beginning of World War II, Lippmann's interest was diverted from problems of political theory to those of international affairs, and it was only with *Essays in the Public Philosophy* (1955) that he returned to his earlier concerns with the political order and democratic structure. The public philosophy, for Lippmann, is a set of positive precepts defining the law that is superior to arbitrary power. It can be discovered by any rational mind, and it is basic to Western institutions. It is the foundation of the good society and must be conscientiously cultivated and transmitted from generation to generation. The liberal democracies, Lippmann charged, have come dangerously close to ignoring the tradition of the public philosophy and accepting politics based on conflict and on interest as legitimate. But political conflict must have limits; and these, like the moral principles that must guide conduct, are to be discovered by reason.

If reason is sovereign, majority voting cannot be trusted, since the voters are too easily swept away by their passions and selfish interests. And their representatives are equally incapable of governing, for they are "insecure and intimidated men . . . [who] advance politically only as they placate, appease, bribe, seduce, or bamboozle, or otherwise manage to manipulate the demanding and threatening elements in their constituencies" (1955, p. 27). As in his first works, Lippmann turned to strong executive power as the practical way out—an executive power enlightened by rationality and constrained by natural law. Such an executive can rule in the interest of "the people"—namely, a "community of the entire living population, with their predecessors and successors" (1955, p. 32)—and not be subject to the whim of the voters.

LIQUIDITY PREFERENCE

"Liquidity preference" is a term that was coined by John Maynard Keynes in *The General Theory of Employment, Interest and Money* to denote the functional relation between the quantity of money demanded and the variables determining it (1936, p. 166). He also used this term, or such variants of it as "liquidity preference function" and "liquidity function," to denote more narrowly the relation between the quantity of money demanded and the

rate of interest (see, for example, p. 168). Since the *General Theory* the term "liquidity preference" has come to be used to refer to the hypothesis or theory that the aggregate quantity of money demanded by the economy will, *ceteris paribus*, tend to be smaller the higher the rate of interest.

Keynes's analysis of the systematic and intimate relation between the demand for money and interest rates and its implications is generally acknowledged to be one of his major contributions to economics. It is one of the two main pillars on which the edifice of the *General Theory* rests, the other being the hypothesis that in a contemporary monetary economy, money prices and especially money wages tend to be rigid in the downward direction (see "Liquidity preference, monetary theory and monetary management," below).

The demand for money

Pre-Keynesian theories. Information about the history of theories of the demand for money may be found elsewhere [see especially MONEY, articles on QUANTITY THEORY and VELOCITY OF CIRCULATION; see also Marget 1938 and Patinkin 1956, pp. 373-472]. It will suffice to recall here that although monetary theorists had long recognized that money is a "store of value" as well as a "medium of exchange," prevailing theories of the demand for money before the *General Theory* tended to stress the role of money as a medium of exchange and the "transaction demand." The two major, broadly accepted formulations before the *General Theory* were that of Irving Fisher and that of the Cambridge school. Fisher (1911) started from the now well-known identity called Fisher's equation of exchange: $MV = PT$, where M is the quantity of money in circulation, T is the volume of transactions, P is the price level, and V is the "transaction velocity of circulation." This equation is also frequently restated as $MV_v = PX = Y$, where X is "real income," Y is money income, and V_v is the "income velocity of circulation." From these identities Fisher derived his theory by hypothesizing (1) that at a given point of time V can be taken as constant (or at least as largely independent of M) and (2) that V tends to change, at best, very slowly over time, being largely determined by institutional and technological factors with a high degree of inertia. The major factors of this kind include the frequency of receipts and disbursements (intimately related in turn to the so-called income period, which is the length of the interval between the dates at which various types of income, such as wages, salaries, and dividends, are typically paid), the degree of synchronization of

receipts and expenditures, prevailing financial arrangements, the rapidity of transportation, and so on. [See MONEY, article on VELOCITY OF CIRCULATION.]

By contrast, the so-called Cambridge school tried to put the explanation of the demand for money into the more familiar format of value theory, i.e., in terms of a demand-for-money equation, $M^d = kY$, an exogenously given supply of money, M , and a clearing-of-market equation, $M^d = M$, implying $M = kY$ (see, e.g., Pigou 1917; Marshall 1923). By comparing this equation with Fisher's equation above, one can readily see that $k = 1/V_v$, i.e., that k is the reciprocal of the velocity of circulation. Indeed, in analyzing the determinants of k and the reasons for its hypothesized stability, the Cambridge school tended to stress largely the same forces on which Fisher's theory rests.

The Fisher and Cambridge models are generally regarded as providing the definitive basis for the so-called "quantity theory of money," a view of very old standing according to which the price level, P , tends to be directly proportional to M . In order for this relationship to follow logically from these models, not only must M not affect V (or k), as those models imply, but also one must suppose that money is "neutral" in the wider sense that it does not affect any of the "real" variables of the system—inputs, outputs, and relative prices, including interest rates. Under this assumption, which, as shown below (see "The significance of liquidity theory under wage flexibility"), might provide a reasonable approximation under conditions of perfect wage and price flexibility, real income, X , may be taken as fixed at the "full employment" level, say \bar{X} . From either the Fisher or the Cambridge equation it then follows that

$$P = \left(\frac{V_v}{\bar{X}} \right) M = \left(\frac{1}{k\bar{X}} \right) M,$$

that is, the price level is proportional to the quantity of money, M .

It should be acknowledged that some of the writers in the Cambridge tradition did at times suggest that the demand for money might depend on wealth and that they did make some occasional references to the possible influence of interest rates (see, for example, Pigou [1917] 1951, p. 166; Lavington 1921, p. 30; Marshall 1923, chapter 4; for still earlier references, see Eshag 1963, pp. 13–14). But they failed to explore systematically the effect of interest rates on the demand for money and the implications of this effect. This failure is even more conspicuous in Fisher. He makes no mention of interest rates in his list of

factors affecting velocity, and although he makes fleeting mention of the "waste of interest" involved in holding money (1911, p. 152), one finds no reference to this passage in the index under the rubric "interest rates."

Two authors who anticipated Keynes in giving adequate recognition to the role of interest rates are Walras, in 1899, and Schlesinger, in 1914 (see Patinkin 1956, notes C and D), but their contributions were largely overlooked at the time. The most significant pre-Keynesian analysis of liquidity preference is generally acknowledged to be that of Hicks (1935), which, however, preceded the *General Theory* by but one year and was partly inspired by Keynes's earlier work, *A Treatise on Money*, published in 1930. This contribution to monetary theory, which in some respects has turned out to be even more influential for further developments than that of Keynes, will be touched upon below.

Keynes's theory. In chapters 13 and 15 of the *General Theory*, Keynes distinguished three "motives" for holding money. The first, the "transaction motive"—sometimes broken down into an income motive and a business motive—corresponds quite closely to the motives stressed by Fisher and the Cambridge school. Like his predecessors, Keynes did not regard transaction balances as being significantly affected by interest rates. The second motive is the "precautionary motive." Under this heading Keynes included balances not earmarked for some definite expenditure in the near future but held instead to "provide for contingencies requiring sudden expenditure and for unforeseen opportunities of advantageous purchases" (1936, p. 196). But why should these balances be kept in the form of idle cash instead of being invested in some kind of readily marketable securities, to be converted into cash if and when the contingency arises? The reason is that the market value of a debt instrument (or "bond"), if it is liquidated before its maturity, is uncertain, even if there is absolutely no risk of default. It depends on the market rate of interest prevailing at the future time of liquidation for loans having a duration equal to the remaining life of the bond: the higher this rate, the lower the market value. This uncertainty about the realization value of a bond would not by itself make bonds inferior to cash as a store of ready purchasing power if the sum of the uncertain liquidation value and the cash interest earned could be counted on to exceed the amount initially invested. However, there can be no such assurance, since between the times of purchase and liquidation interest rates could rise sufficiently to produce a capital loss in excess of the interest

earned. Keynes suggested in particular that the likelihood of a net loss would be larger the smaller the yield of the bond originally acquired. This is because the smaller the yield, the smaller the rise in the rate of interest (in absolute as well as in percentage terms) that will produce a capital loss sufficient to wipe out the accrued interest earned. Furthermore, Keynes suggested that if the current rate is low by historical standards, it will usually be regarded as more likely to rise than to fall. He concluded that the lower the current rate, r , the stronger the incentive to hold precautionary reserves in the form of cash instead of securities. Therefore the (real) demand to hold money for precautionary reasons will tend to be inversely related to r . At the same time, somewhat surprisingly, Keynes did not appear to regard precautionary balances as very sensitive to r . Accordingly, much of the time he lumped together the demand for transaction and for precautionary reasons and regarded the sum, which he labeled M_1 , as primarily controlled by—or a function of—current income. Thus, in his notation $M_1 = L_1(Y)$, where the function L_1 denotes the demand for money resulting from the transaction and precautionary motives.

The third and remaining source of demand for money is the speculative motive, a rather complex mechanism that Keynes had partly anticipated in *A Treatise on Money* (1930). In essence, speculative balances are balances held in cash rather than invested in (long-term) bonds, not just because of the risk that interest rates might rise but rather because of a definite expectation that the price of long-term bonds is likely to fall, and at a rate that more than offsets the interest earned by holding them. A person entertaining such an expectation would prefer to hold cash yielding nothing rather than invest it in what he regards as overpriced long-term bonds that would yield him a negative return. Since the price of long-term bonds varies inversely with long-term interest rates, we may equally well characterize speculative balances as those held by persons who regard the current long-term rate as untenably low and about to rise sufficiently rapidly.

The real significance of the speculative motive is that it may significantly impair, or even thwart altogether, efforts of the central bank to reduce long-term interest rates to the extent necessary to maintain investment at the level consistent with full utilization of resources (see "Liquidity preference, monetary theory, and monetary management," below). Normally, the central bank can expect to enforce lower long-term interest rates, or higher prices of long-term bonds, by buying such

bonds with newly created money. Suppose, however, that a large portion of the market holds definite views about the minimum maintainable level of the long-term rate and hence the maximum maintainable level of bond prices. If, then, the bank attempts to bid up the price of bonds to that maximum or beyond, it will find the public prepared to dump a large portion of its long-term bond holding. The bank will therefore have very little success in lowering the long-term rate, even though it is prepared to acquire a large volume of bonds and to expand the money supply correspondingly. What happens in this situation is that the increase in the money supply is absorbed, not by an increased transaction demand, but by an offsetting increase in the speculative demand, with a resulting fall in the velocity of circulation. In other words, the expansion in M , instead of achieving the desired expansion in income, Y , that would occur if V , the velocity of circulation, remained constant, tends to generate an offsetting change in V , with little effect on Y . A situation of this type has come to be known in the Keynesian literature as a "liquidity trap."

Keynes denoted speculative balances by M_2 and wrote the demand function for such balances as $M_2 = L_2(r)$, where L_2 is a decreasing function of r (1936, p. 199). This formulation—that M_2 increases as r falls—is somewhat misleading, since presumably M_2 should depend not on r as such but only on r in relation to the prevailing market expectations about the maintainable rate, say r^e . Nor can r^e be supposed to stay constant through time or to be uniquely related to r itself. Keynes's formulation might be defended as a useful "short run" approximation: at a given point in time, r^e can be taken as a constant or, at least, as changing more slowly than r . Hence, a fall in r would necessarily imply a fall relative to r^e and thus a rise in M_2 (*ibid.*, pp. 201–202). Under this interpretation, however, one should be aware that L_2 may be subject to significant shifts through time as a result of shifts in market expectations.

The sum of the transaction and precautionary demand, M_1 , and the speculative demand, M_2 , is the total demand for money proposed by Keynes: $M = M_1 + M_2 = L_1(Y) + L_2(r)$ (*ibid.*, p. 199). The Keynesian literature has tended to de-emphasize the sharp distinction between the three motives for holding money and to write the demand for money in the more general form $M = L(r, Y)$. There has also been a tendency to minimize the role of interest expectations, r^e , and to associate the liquidity trap with a low absolute level of the interest rate.

The implied relation between M and r for a

Figure 1 — Relation between the demand for money and the interest rate

given value of Y , say Y_0 , is shown in Figure 1 by the curve labeled L_0L_0 . (The choice of coordinates is dictated by the economists' peculiar convention, popularized by Marshall, of representing demand curves with the quantity demanded measured on the abscissa and the price on the ordinate.) The quantity of money demanded increases continuously as r falls, until, for some sufficiently low value, r_m , the liquidity trap is reached and the curve becomes horizontal (the demand becomes infinitely elastic). Alternatively, the demand curve might be drawn to approach the level r_m asymptotically. Just how low r_m may be depends somewhat on "institutional" factors and on whether r is understood to be the long-term or the short-term rate. But we can, with complete generality, place a lower bound on r_m : in a monetary economy, r_m can never be more negative than the (marginal) cost of storing money. In particular, when money is an intangible, the cost of storing it (at least in the form of bank deposits) is essentially zero, and therefore r_m cannot be (significantly) negative. Indeed, a negative r can be regarded as a premium paid by the lender to the borrower for carrying money over; for example, a short-term rate of -2 per cent per period means that the lender is willing to pay \$100 to receive only \$98 at the end of the period. If the cost of storing is less than 2 per cent, everybody would wish to borrow indefinitely large amounts, since by merely holding the money one would earn the excess of 2 per cent over storage costs. This implies in particular that with a zero

(marginal) storage cost, at a negative rate of interest the demand for money must become indefinitely large—or, equivalently, that no matter how large the quantity of money, r can never be negative. Hence, the demand curve must tend to approach a horizontal asymptote, $r = r_m$ (or possibly reach it from above for some finite M and become discontinuous). Furthermore, r_m cannot be lower than zero (quite generally, it cannot be more negative than the marginal cost of storing money), although it may well be higher, as in Figure 1.

The curve labeled L_1L_1 illustrates the effect on the demand for money of increasing Y , say from Y_0 to $2Y_0$ in Figure 1. Clearly, the demand for money must then be greater at any given rate r ; that is, LL must shift to the right. The relation between L_0L_0 and L_1L_1 becomes especially simple if the demand function $L(r, Y)$ takes a more specialized form, which was suggested, for example, by Pigou (1917) and tested by Latané (1954; 1960) and which has been gaining favor in recent writings—namely, $M = k(r)Y = Y/V(r)$. This formulation provides an obvious bridge between Keynes's original formulation and the received Fisher and Cambridge models. It implies that for a given r the fraction k (or the velocity of circulation, V) will be constant but that k will tend to fall (or V to rise) as the rate of interest rises. In terms of Figure 1, it implies that L_1L_1 is obtainable from L_0L_0 by multiplying by 2 the abscissa value of L_0L_0 corresponding to any given r . More generally, it implies that the LL curve corresponding to any given Y is simply the graph of $k(r)$, up to a proportionality factor, Y . Similarly, the graph of $V(r)$,

Figure 2 — Velocity of circulation and the interest rate

the velocity of circulation as a function of the interest rate, is the graph of the reciprocal of L_0L_0 up to a proportionality factor, $1/Y_0$. The general shape of the graph of $V(r)$ is shown by the vv curve of Figure 2.

Post-Keynesian developments. As indicated earlier, post-Keynesian developments of liquidity theory were inspired not only by Keynes's *General Theory* but at least as much by two germinal ideas advanced by Hicks (1935). Hicks's first suggestion was that the major reason why transactors hold money balances having little or no yield when they could invest them in a large number of income-yielding assets, some at least not significantly less safe than money, is to be found in the costs and the "bother" of the transactions necessary to move from money into earning assets and back to money (p. 19).

The portfolio approach. Hicks's second suggestion was that the theory of the demand for money must be developed out of a more general theory of the allocation of wealth among various assets. This theory, Hicks suggested, should be analogous to the standard theory of consumers' choice, except that the object of choice, instead of being consumption flows, would be the various stocks appearing on the asset and liability side of the balance sheet, and prices would be replaced by expected yields. He saw this substitution as presenting a real challenge, since yields in contrast to prices would have to be recognized as uncertain, and this uncertainty in turn would have important implications for the nature of choices.

Both ideas have been extensively pursued with the help of the emergence of the theory of choice under uncertainty [see DECISION MAKING, article on ECONOMIC ASPECTS]. At present the major differences of view between monetary theorists (and they are not very major) seem related to the relative importance assigned to each of Hicks's two ideas.

Among those who have pursued the portfolio, or wealth, approach, the formulation of Friedman (1956), developed in numerous writings, has been particularly influential [see MONEY, article on QUANTITY THEORY]. Friedman views the demand for money as being determined by wealth (broadly understood as the present value of expected net future receipts from all sources), by the distribution of wealth between human and nonhuman (i.e., marketable) wealth, by the expected yield of all major types of assets that are alternatives to money as ways of holding wealth, and by the "utility attached to the services rendered by money" relative to other assets—namely, bonds, equities,

and physical commodities. By combining this theory with his suggestion (1957) for ways of approximating wealth (or, more precisely, "permanent income," which is, however, essentially proportional to wealth as defined above) Friedman has endeavored to cast his theory in testable form and actually to test it (1959). He has concluded that his model fits the facts well, in that the demand for money increases with wealth and more than in proportion, although he can find little evidence that interest rates in fact play a significant role.

Other authors have been more concerned with developing and refining theoretical aspects of the Keynes-Hicks approach (see the very useful survey provided by Johnson 1962). Among their attempts, especially worth noting are the recent contribution of Turvey (1960) and the elegant formulation of the theory of choice between money and bonds of various maturities developed by Tobin (1958) along the lines of the modern theory of portfolio selection.

Transaction costs and the Neo-Fisherian approach. The portfolio approach suffers from one major inadequacy. As long as there exist any interest-bearing obligations that are issued by credit-worthy borrowers and are of sufficiently short maturity—for example, redeemable on demand or on very short notice—it is impossible to explain why any portion of the portfolio should be held in the form of money, yielding less or nothing at all—except by explicit analysis of the role of transaction costs.

Even Keynes's stricture that, for sufficiently low interest rates, money may dominate bonds because of the uncertainty of the realization value cannot apply to short maturities or demand loans. These instruments dominate money in every possible dimension: they are equally safe, they yield an income, and they can be converted into the medium of exchange, if and when it is needed, at face value. Why, then, should anyone hold money, except for the very instant he receives a payment or is about to make one? The necessary and sufficient condition, as Hicks rightly pointed out, is that out-of-pocket costs and the effort required in moving from cash to bonds and back to cash exceed the yield. At first sight these transaction costs may appear too trivial to account for any substantial holding of cash, let alone for the observed cash holdings. (Aggregate cash holdings of U.S. consumers at the end of 1963 were estimated to represent slightly less than two months' income.) But this casual impression is misleading. It is well known, for instance, from the theory of optimum

inventory holdings that transaction costs do account for a substantial portion of inventories held by business (which in the United States amount to some three months' sales). This parallel between business inventories and cash holdings is not fortuitous, for in many respects the holding of a stock of cash by transactors is closely analogous to the holding of a stock of goods by business. In fact, Allais (1947, chapter 8a) and Baumol (1952) pioneered in showing that the holding of cash balances could be analyzed by a straightforward application of the so-called lot-size formula of inventory theory: in order to avoid incurring too frequently the costs involved in transforming securities into cash, it pays to secure cash in a bulk or "lot" that will take care of expenditure requirements for a certain length of time, even though interest will be forgone on the amount withdrawn. Similarly, if a transactor is receiving money in a more or less continuous trickle, it will pay to accumulate a "lot" before investing it. The size of the lot, and hence the average cash balance held relative to the rate of outpayments (or receipts), which corresponds to the Cambridge k or to the reciprocal of the velocity of circulation, will be positively associated with the size of transaction costs and inversely associated with the rate of interest. Tobin (1956) refined and improved on this analysis, applying it more specifically to the consumer receiving his income in bulk at income-payment dates and spending it gradually over the income period.

Although these contributions are to be regarded as illustrative rather than as aimed at deriving an exact demand equation for money, they do point up one very fundamental principle. The amount that can be earned by investing an amount of cash, m , that will not be needed to meet expenditures for some span of time, t , in a security yielding r per cent per year, is approximately $m(tr - c)$, where c is the brokerage fee, if any, per dollar of investment. The investment will not be worthwhile unless this product exceeds the lump-sum cost of the two-way transaction, including both the out-of-pocket and the bother costs. To illustrate the order of magnitudes involved, suppose that a person earns \$12,000 a year, paid monthly; he then receives \$1,000 once a month. Suppose he spends these receipts at an even rate. He might then consider keeping half the sum for current expenditure and investing the remaining half, or \$500, which he will not need until the first half is exhausted—that is, for half a month. Suppose the yield of a 15-day security, net of commissions, is 3 per cent per year; then all he stands to earn

from the transaction is $\$500 \times .03/24$, or a mere 62.5 cents. If the two-way transaction cost and bother exceeds this, he will invest none of the monthly receipts and thus will end up holding, on this account, an average cash balance of \$500, or $1/24$ of his (annual) income. Note that if he were paid twice as frequently—that is, \$500 every two weeks—it would a fortiori not pay him to bother, and he would be holding an average cash balance of \$250, or $1/48$ of his income.

The conclusion to be drawn from these illustrations can be summarized as follows: In a money-using economy, transactors are paid in money and in turn must pay in money; lack of synchronization between receipts and payments gives rise to pools of money that will not be needed for some length of time. Given the rate of return and the cost and effort of transactions, it will not pay to invest such pools unless the product of their size and the length of the "idle" time exceeds some critical threshold level. Thus, the basic reason for holding idle cash balances is not that they provide a useful service but simply that it does not pay to shed them. Obviously, given the rate of interest, the extent to which it does not pay to shed idle money, and thus the average cash balance held, will depend on such institutional-technological factors as (a) transaction costs—the higher the cost, the smaller the incentive to shed; (b) the size and nature of the transactor's business—large transactors may be confronted with pools so large that it pays to shed them even for very short periods, and they may also have an incentive to set themselves up so as to minimize marginal transaction costs; and (c) the frequency of income payment and settlement dates—the greater the frequency, the smaller the average cash balance. But these are, by and large, precisely the factors emphasized by Fisher in explaining the determinants of the velocity of circulation. The new element is the recognition that given all these factors, the average cash balance demanded will tend to fall with the rate of interest, which provides the incentive to shed.

How does the Keynesian liquidity trap fit into this model? The first point to be noted is that Keynes's theory of the speculative demand suffers from his excessive concentration on long-term bonds as the alternative to cash, to the neglect of short-term instruments. The proposition that people will flee from long-term bonds when the price of those bonds is deemed to be untenably high seems valid enough, but the obvious abode for the funds accruing from moving out of long-term bonds should be short-term ones, not cash.

However, a massive endeavor to move from long-term into short-term instruments will unavoidably depress short-term rates, perhaps to such an extent that for many investors the investment will no longer be worth the effort. Thus, they may eventually end up holding cash, but because of the low level of short-term rates, not directly in response to the low level of long-term rates. In short, the central bank's endeavor to depress long-term rates by buying bonds and increasing the money supply can always be counted on to depress short-term rates. However, it may not be very successful in depressing long-term rates to the desired extent, except insofar as a persistent low level of the short-term rate may eventually persuade the public that the long-term rate is really not unreasonably low. A good example of such a development is provided by the United States in the late 1930s. Because of a sizable monetary expansion after 1932, by 1939–1940 the short-term rate on government bills had been driven down very nearly to zero (below $2/10$ of 1 per cent), but the long-term rate on high-grade bonds was still hovering around 3 per cent (down from about 4.7 per cent in 1929). In this sense the Keynesian liquidity trap must still be acknowledged as a possible serious hindrance to the effectiveness of monetary policy. And in any event, the proposition that no market rate—long or short—can ever be negative retains its validity.

The theory that emerges from the preceding discussion emphasizes the flow of transactions (and therefore income rather than wealth) and interest rates, especially the short rate and the rate on savings deposits, as the main arguments of the demand function for money. It further suggests that the parameters of this function are largely determined by the forces emphasized by Fisher and should therefore tend to change at best slowly through time. Because the model represents an obvious blend of the motives emphasized by Fisher and by Keynes and Hicks, we have referred to it as the Neo-Fisherian approach (although this terminology is not in general use).

Although the contrast between the "portfolio" approach and the "transaction" approach has deliberately been emphasized here, it is well to recognize that the difference between these two models is minor—largely a matter of relative emphasis—both in principle and in terms of practical implications. In particular, these models concur in the conclusion that the demand for money should be "homogeneous of first degree in current prices"—that is, that a change in the price level, other things being equal, should give rise to a propor-

tional change in the demand for money while leaving unaffected "real demand" (demand measured in terms of purchasing power over commodities).

Empirical verification. Since the appearance of the *General Theory*, considerable effort has been devoted to assessing empirically the responsiveness of the demand for money to variations in interest rates and more generally to estimating demand functions for money and testing their stability (see, for the United States, Johnson 1962, pp. 354–357).

These investigations have tended to confirm that the demand for money is positively and closely associated with income or wealth or both and that a change in the price level tends to result in a proportional change in demand. They have also overwhelmingly tended to confirm that this demand is significantly responsive to changes in interest rates in the direction hypothesized by Keynes. The only significant exception in this regard is Friedman's results, cited in the section "The portfolio approach," above. His contrary conclusions, however, have been criticized for being very much dependent on the specific definition of money he uses (which includes means of payment and some, but not all, savings deposits), on the specific period chosen for his tests, and on his statistical techniques. They have also been criticized because his model, although it apparently fits the period from the second half of the last century to the late 1940s quite well, is not able to account for the very significant rise in velocity that has occurred since the beginning of the 1950s, concomitantly with the marked rise in interest rates. In particular, Meltzer (1963) and Brunner and Meltzer (1964), who otherwise fully sympathize with Friedman's basic theory, have found marked and significant interest-rate effects, whether one uses as additional variables income, or permanent income, or a measure of nonhuman wealth. The major novelty in their results is the strong showing of the nonhuman wealth variable as compared with current income, although these results contrast with those reported by other investigators using a different measure of wealth (e.g., Bronfenbrenner & Mayer 1960). On the whole, it seems fair to say that at the moment the evidence is not adequate for the fine discrimination between the wealth and the neo-Fisherian formulations of the demand for money.

Liquidity preference, monetary theory, and monetary management

The Keynesian revolution. As suggested earlier, the two major analytical contributions of the *Gen-*

eral Theory are the hypotheses of liquidity preference and of wage rigidity. The systematic analysis of the implications of these two highly fruitful hypotheses and their interaction was made more powerful and incisive by a third novelty, which is primarily methodological. This is the development of "aggregative analysis," or what has since come to be known as macroeconomic analysis. Economists had long before been used to analyzing economic variables as reflecting the interaction of simultaneous relations, and the notion of equilibrium was used precisely to denote the value of the variables simultaneously satisfying all the relevant relations. However, before the *General Theory* this method of analysis was generally applied in so-called "partial equilibrium analysis," that is, the study of some portion of the economy—say, the market for a particular commodity or a group of interrelated commodities. The method had also been applied with some success, largely by Walras, to the economy as a whole in "general equilibrium analysis," which formally recognizes the interactions of all possible markets, treating the economy as a very large scale closed system of simultaneous equations. The novelty of aggregative analysis consists in lumping together a large number of commodities having common characteristics for the problem at hand and treating the aggregate as a single commodity. This approach makes possible the approximation of the whole economy with a small system of simultaneous relations, and, by permitting closer scrutiny and understanding of the interactions, it has proved to be highly fruitful.

Analysts of Keynes's work have correctly pointed out that none of these basic ingredients of the *General Theory*—liquidity preference, wage rigidity, or the aggregative approach—was entirely new. We have documented this point above with respect to liquidity preference. The novelty consisted in the mastery way in which the ingredients were blended, which enabled Keynes to provide an analytical explanation of the phenomenon of unemployment and its possible persistence in an advanced capitalistic economy and to shed new light on the role and limitations of monetary and fiscal policy in controlling the level of employment and prices. It is this achievement, and its enormous impact on economics, that has since come to be known as the Keynesian revolution.

The rest of this section, relying largely on aggregative analysis, endeavors to sketch out the role of liquidity preference, first under the classical assumptions of perfect wage and price flexibility and then in combination with the empirically far more relevant hypothesis of downward wage rigid-

ity. Our focus is primarily on the significance of liquidity preference as seen today, some thirty years after the appearance of the *General Theory*, rather than on summarizing or criticizing Keynes's original formulation. Accordingly, in what follows, the post-Keynesian elaborations are freely drawn upon.

The basic model. In Keynes's *General Theory* and, more particularly, in later endeavors by other authors to formalize its message (e.g., Hicks 1937; Lange 1938; Modigliani 1944; 1963; Patinkin 1956), the whole economy is reduced (explicitly or implicitly) to four aggregates: aggregate output, X ; labor, N ; money, M ; and bonds, B . For each of these aggregate commodities there is a "market" characterized by supply conditions, demand conditions, and the "clearing-of-market" or equilibrium requirement that demand must equal supply. Demand and supply, in turn, are controlled by three prices or terms of trade between each commodity and money: P , the price of output (the "price level"); W , the price of labor (the "wage rate"); and $1 + r$, the number of dollars obtainable next period by lending a dollar today, where r is the rate of interest. To understand the mechanism determining the level of economic activity in a given short interval and the role of liquidity preference, we must examine the structure of the four markets and their interaction.

The demand for output in the commodity market, usually referred to in the literature as "aggregate demand" and denoted here by X^d , is a central construct of Keynesian analysis. It has given rise to a voluminous literature, both theoretical and empirical, which can be summarized here very briefly, since it is covered in other articles [see in particular *INCOME AND EMPLOYMENT THEORY*; *CONSUMPTION FUNCTION*; *INVESTMENT*, article on *THE AGGREGATE INVESTMENT FUNCTION*]. Two sources of demand are distinguished: current consumption, C , and investment demand, I —i.e., demand for current output destined to increase the stock of productive capital. Thus, $X^d = C + I$. Theoretical considerations, and the empirical evidence, suggest that consumption in turn is primarily controlled by (a) the level of real income that, disregarding for the moment the fiscal activity of the government sector, can be equated with aggregate output, X ; (b) net real private wealth, A ; and possibly (c) the rate of interest, r . This can be formalized by means of the "consumption function," $C = C(X, A, r)$. Investment demand can be taken to be positively associated with aggregate output and negatively associated with the rate of interest and the pre-existing stock of capital, K_0 ; thus,

$I = \mathcal{I}(r_0, X, K_0)$. Finally, net private real wealth, A , the sum of all privately held assets minus private debt, can be expressed as $A = K_0 + G/P$; that is, it consists of the stock of capital plus the money value of the outstanding government debt, G , deflated by the price level, P , to express it in terms of purchasing power over output.

The four equations given above can be conveniently reduced to a single one by first substituting for A in the consumption function and then substituting this function and the investment function into the definition of aggregate demand:

$$(1) \quad X^d = \mathcal{C}(X, K_0 + \frac{G}{P}, r) + \mathcal{I}(r_0, X, K_0).$$

Next, we observe that in equilibrium, aggregate demand X^d must equal aggregate supply, or

$$(2) \quad X = X^d.$$

We use this property to replace X with X^d in the right hand side of (1). The resulting equation contains X^d on both sides of the equality. We can, however, "solve" the equation explicitly for X^d , obtaining finally an expression of the form

$$(1') \quad X^d = D\left(r, K, \frac{G}{P}\right),$$

which will be referred to hereafter as the aggregate demand relation. Note that aggregate demand, X^d , may be expected to be negatively associated with r . This is because an increase in r will reduce investment demand directly, and this reduction, in turn, will reduce aggregate demand even further by means of its depressing effect on consumption demand, which depends on total output—this is the so-called multiplier effect [see CONSUMPTION FUNCTION]. Insofar as investment demand itself depends on output, X^d may in fact not decrease continuously as r rises, but this complication will be ignored here.

To complete the description of the output market, we also need an "aggregate supply function." Aggregate supply, X , may be expected to be positively associated with (a) the price, P , at which firms can sell their output relative to the wage rate, W , they must pay, or P/W , and (b) with the pre-existing capital stock, K_0 (on the convenient approximation that the increment in the stock of capital resulting from current investment will not become productive until the next period); thus,

$$(3) \quad X = S\left(\frac{P}{W}, K_0\right).$$

In the labor market, the aggregate demand for labor, N , can be inferred from the so-called aggregate

production function, relating output, X , to the input of labor and the stock of capital, K_0 . This function implies that N can be expressed in terms of X and K_0 , say, $N = F(X, K_0)$. It is, however, more convenient to replace X in this equation with the right-hand side of (3), thus obtaining the "labor demand" equation

$$(4) \quad N = \mathcal{N}\left(\frac{P}{W}, K_0\right).$$

The description of the supply side of the labor market is a somewhat more complex task, for it is here that we must formalize the Keynesian notion of "downward wage rigidity." In its broadest sense, this term connotes the absence of "wage flexibility," of a state of affairs in which money wages fall promptly whenever the supply of labor exceeds the demand for it and keep falling as long as the excess supply persists. In a narrower definition, it means that the current money wage will not be bid below some floor level, W_0 (reflecting the past history of the system), no matter how large the excess supply of labor—though it can be freely bid up in response to excess demand for labor. For present purposes, we shall rely on this narrower version, which we label "absolute" rigidity, because it is more readily formalized. However, the conclusion of the analysis below would not change qualitatively if the wage rate had some tendency to fall for sufficiently large unemployment and falling prices, as long as the reaction was sluggish and unsystematic. There can be little doubt that wage rigidity in this sense is, and has been for some time, a feature of free market economies.

To formalize the hypothesis of absolute wage rigidity we need to introduce the notion of a "potential supply of labor function," say, $\mathcal{S}(W/P)$, which gives the level of employment "desired," or labor force available, at any given real wage, W/P . Now, let E denote the actual level of employment. Then absolute wage rigidity can be expressed as follows:

$$(a) \quad W = W_0, \quad \text{if } \mathcal{N}\left(\frac{P}{W_0}, K_0\right) < \mathcal{S}\left(\frac{W_0}{P}\right),$$

(5)

$$(b) \quad E = \mathcal{S}\left(\frac{W}{P}\right), \quad \text{if } \mathcal{N}\left(\frac{P}{W_0}, K_0\right) \geq \mathcal{S}\left(\frac{W_0}{P}\right),$$

$$(6) \quad E = N.$$

Line (a) of (5) states in essence that if at the rigid wage W_0 the demand for labor falls short of the potential supply, then the actual wage rate will coincide with W_0 . Employment, being equal to the demand for labor as stated by (6), will then fall short of the potential supply, and the differ-

ence will represent the so-called involuntary unemployment. If, however, at W_0 the demand exceeds the potential supply, then line (b) of (5) becomes applicable: the floor level loses its relevance, and the actual wage will have to rise enough to equate the demand with the potential supply. This formulation of wage rigidity has the advantage that it can encompass wage flexibility as a limiting case, in which we assign to W_0 a value so small that the relevant portion of (5) will necessarily be line (b).

In the money market, the demand, M^d , can be expressed as $M^d = L(PX, PA, r)$, where L is, of course, the liquidity preference function that (in recognition of the two major points of view summarized in the section "Post-Keynesian developments" of liquidity preference) is written as a function of both money income (PX) and wealth (PA). By expressing A in terms of its components, K_0 and G , and using the property that a change in the price level should tend to give rise to a proportional change in the demand for money, the preceding equation can be rewritten as

$$M^d = PL(X, K_0 + G/P, r).$$

However, for the purpose of the graphical analysis that is developed below, we shall frequently find it convenient to rely on the specialized version $M^d = PX/V(r)$, where $V(r)$, it will be recalled, denotes the velocity of circulation as a function of the rate of interest. As to the supply side, unless otherwise specified, it will be assumed that money is created by the banking system in the process of purchasing debt instruments (bonds) issued either by the private sector or by the government, and that the total supply of money, M , is exogenously determined through central bank policy. Since in equilibrium we must have $M^d = M$, the description of the money market can be reduced to a single equation obtained by replacing M^d with M in the above equations:

$$(7) \quad M = PL(X, K_0 + \frac{G}{P}, r),$$

or

$$(7') \quad M = \frac{PX}{V(r)}.$$

Equations (1) to (7) involve seven endogenous variables: X^d , X , N , E , P , W , r . They therefore form a closed system whose solution describes the short-run equilibrium of the economy. This solution also depends, of course, on the parameters of the various equations, on initial conditions, such as K_0 and G , and on policy variables, of which in the present case there is but one, the money supply, M . The demand and supply for the remaining commodity,

namely, bonds, B , are not explicitly displayed in the system because, by a well-known principle called Walras's law, it can be shown that the demand and supply for one commodity out of the set of all commodities are necessarily equal when all other markets are "cleared" (that is, when demand equals supply); we choose the bond market as the redundant one (Modigliani 1963).

With the help of this system we can now focus on the role of monetary forces, in particular that of liquidity preference, in the determination of equilibrium, beginning with the classical assumption of wage flexibility.

Wage flexibility. As already noted, under the assumption of wage flexibility the labor supply conditions are fully described by line (b) of equation (5). But this equation, together with that for labor demand, equation (4), and the equilibrium condition (6), turns out to involve only three variables: N , E , and P/W (or its reciprocal, the real wage). They therefore form a closed subsystem which can be solved independently of the rest. This solution yields the equilibrium real wage, W/P (where "" denotes an equilibrium value), and employment, \hat{N} (which is also "full employment" since it coincides with the labor supply). From (3) we can then infer the equilibrium or full-employment level of output, \hat{X} .

At this point it becomes useful to distinguish two possible cases, the one in which there is no national debt and the one in which there is.

No national debt. Referring back to the aggregate demand relation (1'), we observe that if G is zero, then the third argument of the aggregate demand function is necessarily zero, no matter what value P may take: in other words, *aggregate demand does not depend on the price level*. (This important implication, it should be noted, depends critically on the approximation implicit in the formulation of the consumption function, that aggregate consumption, C , depends only on aggregate net wealth, not on its distribution between households. Changes in the price level will of course affect the demand of individual consumers by causing redistributions of wealth between creditors and debtors, but our aggregative assumption implies that such redistributions will affect only the distribution of consumption between households, without affecting the total.) Since K_0 is a given initial condition, it can be seen that the right-hand side of (1') contains only one variable, r . It follows that from (1') we can infer the equilibrium value of r , \hat{r} , which makes the aggregate demand, X^d , equal to the aggregate supply, \hat{X} . Next, substituting \hat{r} and \hat{X} into the money-market equation

Figure 3 — Equilibrium under wage flexibility

(7), we can determine the price level \hat{P} that equates the demand for money with the given supply (provided such a value of P exists; see below). Finally, from \hat{P} and the equilibrium real wage, \hat{W}/\hat{P} , we can infer the equilibrium money wage, \hat{W} .

The nature of the solution can be clarified by means of Figure 3, in which X is measured on the ordinate and r on the abscissa. The horizontal line labeled SS , cutting the ordinate at \hat{X} , represents the aggregate supply consistent with full employment—that is, with the clearing of the labor market. It is a horizontal line because, as should be apparent from the derivation above, the value of \hat{X} does not explicitly depend on r . The curve labeled DD is the graph of the aggregate demand relation (1'), which is shown falling from left to right for the reasons stated earlier. Equilibrium in the commodity (and labor) market is thus represented by the point of intersection of the demand and supply curves, namely, point a , with coordinates (\hat{X}, \hat{r}) .

There remains to be shown the role of money and the money market in the determination of equilibrium. For this we refer back to equation (7') and note that for a given value of M/P this equation expresses a relation between the two variables X and r . It is therefore amenable to graphical representation in our figure. Indeed, the shape of this graph can be readily inferred by solving (7') for X to obtain $X = V(r)(M/P)$. Given M/P , the graph of this equation is simply that of $V(r)$, already shown in Figure 2, except for a proportionality fac-

tor and for the fact that the axes are interchanged, r now being measured on the abscissa instead of the ordinate. The result is a curve such as $M'M'$, which represents the locus of (7') for an arbitrarily chosen value of the "real" money supply, (M/P) . It rises from left to right because, as r increases and transactors are induced to economize on their cash holdings, the velocity of circulation increases, and thus a given "real" money supply is capable of financing a larger and larger volume of transactions, X .

It should be readily apparent that the curve corresponding to some other value of M/P , say, a value m times larger, can be obtained from the $M'M'$ curve by multiplying by the factor m the ordinate of the $M'M'$ curve corresponding to any given value of r . It follows that provided \hat{r} (the abscissa of point a) is to the right of r_m there will be some unique value of M/P , say, \hat{M}/\hat{P} , such that the corresponding MM curve will go through the point of intersection, a , of the other two curves. This unique curve is represented by $\hat{M}\hat{M}$ in the figure. Thus, with a real money supply \hat{M}/\hat{P} , the money market as well as the commodity and labor markets will all be simultaneously cleared with the output \hat{X} and the rate of interest \hat{r} . But this in turn means that, given the actual money supply M , the price level must tend to the equilibrium level \hat{P} , such that $M/\hat{P} = (\hat{M}/\hat{P})$, or $\hat{P} = M/(\hat{M}/\hat{P})$. Similarly, $\hat{W} = \hat{P}(\hat{W}/\hat{P})$, where (\hat{W}/\hat{P}) is the full-employment equilibrium real wage. A higher value of W and P would make the money supply inadequate to transact the full-employment income, unless the rate of interest were higher than \hat{r} . But a higher r would reduce the aggregate demand below the full-employment supply. This in turn would cause unemployment which, with flexible wages, would lead to a fall of W and hence of P to the equilibrium levels \hat{W} and \hat{P} ; the converse would be true for values of P and W below the equilibrium levels.

There are three main implications of this analysis to which attention must be called:

(a) Provided $\hat{r} > r_m$, the only economic effect of M is to determine the price level \hat{P} ; furthermore, it is apparent from the derivation of the last paragraph that \hat{P} is proportional to M , so that, in this sense, the quantity theory of money holds.

(b) The equilibrium value of P corresponding to a given M depends, not only on full-employment output \hat{X} , which controls the position of SS , and on slowly changing institutional factors determining the shape of $V(r)$, but also on r . As can be seen from Figure 3, the larger \hat{r} is, the smaller will be

the equilibrium real money supply. But \hat{r} , for a given \hat{X} , is in turn associated with the position of the aggregate demand relation, DD . A rise in the aggregate demand relation—reflecting an increase in consumption or investment demand or both at each level of income and of the interest rate—will result in an upward shift of the DD curve, and this in turn will move to the right the point of intersection, a , of aggregate demand and supply, increasing its r coordinate. Such a shift is illustrated by the curve $D'D'$ intersecting SS at a' . If in the face of such a shift the central bank does not force an appropriate contraction in M , excess demand will arise in the commodity and labor markets that will force wages and prices up. This will reduce the real money supply, lowering the MM curve, until a value of P is reached such that MM coincides with $M'M'$. If the price rise is to be avoided, the central bank must enforce an appropriate reduction in M (in the same proportion in which prices would rise otherwise). We deduce that once liquidity preference is recognized, if the monetary authority is concerned with maintaining the stability of the price level over time—as it must be if a monetary economy is to work smoothly—it must actively manage the money supply, enforcing a (relatively) larger money supply, and a smaller value of r , when demand tends to be slack and a relatively smaller supply, and higher r , when demand tends to be more active.

(c) Suppose, however, that in some period demand is slack and the DD curve is so depressed that it intersects SS at a value of r smaller than r_m , as illustrated by $D''D''$ intersecting SS at b in Figure 3. It is then apparent that there can be no possible value of M/P such that the corresponding MM curve will go through b , since regardless of the value of M/P , every MM curve must lie entirely to the right of r_m . In this situation, sometimes referred to as "the Keynesian case" or "the special Keynesian case," the economic system will not have any equilibrium solution (a set of prices and interest rates that can simultaneously equate all demands and supplies). If prices and wages are flexible, they will both tend to fall indefinitely under the pressure of excess supplies. But this fall, which under normal conditions would re-establish equilibrium by shifting MM up, can now never prove sufficient. By the same token, monetary policy also breaks down: there is no feasible expansion of the money supply sufficient to eliminate the excess supply of goods and labor.

Thus, from liquidity preference Keynes was able to derive the important and novel result that under certain conditions an economy using a token money

may simply break down, having no maintainable position of equilibrium (except through government fiscal policy or wage rigidity, which will be discussed below).

Positive national debt. The government debt, G , may consist of interest-bearing instruments (government bonds) or government fiat money or both, circulating along with or instead of the money created by the banking system. In any case, if G is positive, it is apparent from equation (1') that aggregate demand depends not only on r but also on P . In terms of Figure 3, equation (1') must now be represented by a family of curves, one for each value of P . For the sake of illustration, suppose that the curve DD in the figure corresponds to the received price level, P_0 . It can readily be established that to a different value of P , say, $P_1 < P_0$, there will correspond a new DD curve higher and to the right, such as $D'D'$. This is because a fall in P will increase the real value of the government debt held by the public and hence the real net worth of the private sector. This in turn will tend to increase consumption demand, and hence total demand, for any given r . Conversely, a rise in P will shift DD downward and to the left.

This dependence of aggregate demand on P when G is not zero has come to be known in the literature as the "real-balance effect," and also as the "Pigou effect" because Pigou called attention to it in a very influential work (1947). However, the point had been made earlier by others, in particular by Scitovsky (1940). The main implication of the real-balance effect is that even with flexible wages the system will in general have a position of full-employment equilibrium. In other words, it rules out the possibility of the "Keynesian case" discussed above. To illustrate this point, suppose that corresponding to the received price, P_0 , the aggregate demand function had the position $D''D''$ in the figure, which could not possibly intersect an MM curve on SS . Since the position of DD now depends on P , as P falls under the pressure of excess supply the DD curve will keep shifting to the right at the same time that MM shifts upward. Except under very special *ad hoc* assumptions, MM and DD will eventually intersect on SS at some point to the right of r_m .

This demonstration that, provided G is positive, a system with flexible wages will possess a position of full-employment equilibrium, contrary to Keynes's conclusion, has been seized upon by some of Keynes's critics as disposing of one of his most significant and novel results. They have concluded that underemployment equilibrium can arise only from wage-price rigidities. This view must be re-

garded as unwarranted, mainly for the following reasons: (a) Keynes's conclusion stands when $G = 0$. (b) Even when $G > 0$, the conclusion that a full-employment solution would exist is valid only under the assumption, implicit in the model, that falling prices do not generate perverse expectations of further falls, which would reduce demand. Furthermore, it ignores the likelihood that a violent deflation, which might be necessary to produce a sufficient increase in the real value of the national debt, would severely disrupt a monetary economy by producing wholesale debtors' insolvency. In view of these considerations, Pigou's demonstration has little practical relevance, as Pigou himself acknowledged ([1947] 1951, p. 251). Even if full employment could be re-established by sufficient deflation of prices and wages, it would be preferable to avoid this outcome by relying on the kind of fiscal policy devices, discussed in the next section, that one would have to fall back on when $G = 0$. To look at the matter in a slightly different light, wage and price rigidity, instead of hindering the working of a monetary economy, may provide it with a degree of price stability that in the long run contributes to its smooth working, even though this rigidity makes the task of successful monetary management more challenging.

Downward wage rigidity. The working of the system when the level of the rigid wage W_0 is sufficiently high to be at least potentially effective can be illustrated by Figure 4, which is a simple variant of Figure 3. For this purpose it is convenient to

Figure 4 — Equilibrium with a rigid wage level (W_0)

introduce a new symbol to denote money income, Y , which is related to other variables of the system by the identity

$$(8) \quad Y = PX.$$

Also, for the sake of exposition we deal formally with the case $G = 0$, with some occasional reference to the (rather minor) modifications called for if this restriction is discarded.

We recall that with $G = 0$ the right-hand side of (1') contains only the variable r . From (1'), (2), and (3) we can then derive a relation between Y/W and r . Here Y/W is income measured in what Keynes called wage units (that is, income measured in terms of labor as a *numéraire*). We first solve equation (3) for P/W in terms of X and write the solution as

$$(3') \quad P/W = \phi(X),$$

a "Marshallian" short-run supply function indicating the price—in terms of the cost of labor—needed to call forth a given supply, X . Next, using (1') and (2), we can express X as a function of r . It follows that Y/W can itself be expressed as a function of r —say, $Y/W = X(P/W) = X\phi(X) = y(r)$. This equation is an obvious variant of the aggregate-demand relation (1'), shown as DD in Figure 3, except that output is expressed in wage units. Accordingly, its graph, shown by the yy curve of Figure 4, bears a close relation to that of DD in Figure 3, from which it differs only by the factor P/W . In particular, yy must fall from left to right if DD does, since P/W is an increasing function of X . The horizontal line ss again represents "full-employment output" in wage units, $(P/W)\hat{X}$, where P/W and \hat{X} can be inferred from the solution of the system under flexible wages. The portion of yy above ss has been dashed to indicate that it can never be "effective," since real income there exceeds the full-employment level.

The curve rising from left to right and labeled \bar{M}/W_0 is again derived from the money market equation (7'), on the assumption that the given money supply is \bar{M} . First solve (7') for PX , obtaining $PX = V(r)M$. Next replace M with \bar{M} and divide both sides by W_0 . This yields $Y/W_0 = V(r)(\bar{M}/W_0)$. Its graph must look like that of MM in Figure 3, for it is again the graph of $V(r)$ up to a proportionality factor \bar{M}/W_0 (instead of M/P , as in Figure 3). It shows the level of income (in wage units) that can be transacted at each level of r , given the money supply in wage units.

If the yy curve and the money-market curve intersect in their effective range—below or on ss —as in Figure 4, then the coordinates of their point

of intersection, labeled a , show the equilibrium value of income, \bar{Y}/W , and of the rate of interest, \bar{r} . If this intersection does not fall on ss , then the equilibrium is one of less than full employment. It is a position of *equilibrium* despite the presence of unemployment because, under wage rigidity, the excess supply of labor does not lead to any further adjustment (at least in the short run). By contrast, if wages were flexible, the excess supply would bid down W which, with \bar{M} given, would raise \bar{M}/W , shifting the MM curve upward and moving its point of intersection with yy upward and to the left until it coincided with the full-employment point, a' in the figure. (If G is assumed to be positive, the fall in W will also tend to shift yy upward, moving a' to the right.)

Even under wage rigidity, output and employment could be increased by increasing the money supply, which, with W given at W_0 , would raise M/W and hence the MM curve. In fact, provided that a' is to the right of r_m , there is an ideal money supply, \bar{M} , that produces an MM curve that intersects yy at a' . Alternatively, the goal of optimal monetary policy might be visualized as that of enforcing the rate of interest that would generate an aggregate demand equal to full-employment output, supplying whatever quantity of money is needed to enforce that rate. In terms of Figure 4, the rate of interest called for is, of course, \bar{r} (which is the r coordinate of a'), and the corresponding quantity of money is again \bar{M} .

This analysis should help to show how the interaction of liquidity preference and wage rigidity makes the task of economic stabilization through monetary policy a highly complex and difficult one. In the absence of wage-price rigidities the concern of monetary policy would be reduced to the maintenance of price stability. And in the absence of liquidity preference the velocity of circulation could be counted upon to be sufficiently stable to make this task a relatively easy one. In a stationary economy it would call essentially for a stable money supply, whereas in an expanding economy it would call for a money supply that keeps pace with the growth of full-employment output, a growth that also appears to be characterized by a fair degree of stability.

But under wage rigidity, monetary policy has the double task of trying to achieve both price stability and full employment. Furthermore, because liquidity preference causes the velocity of circulation to vary with interest rates, the money supply needed to reach these goals will vary, relative to full-employment output, with variations in aggregate demand conditions. In terms of Figure 4,

a rise in consumption or investment demand relative to income will shift the yy curve to the right; a corresponding fall will shift it to the left. These shifts have to be countered by contrary adjustments of the money supply relative to the level of full-employment output. Furthermore, failure to adjust the money supply properly will tend to have asymmetrical consequences. An excessive money supply will still give rise to increases in prices that could have been avoided and that are largely irreversible. But too small a money supply will result in an insufficient aggregate demand that, aside from deflationary effects on the price level, will result in the waste and social scourge of unemployment.

Note also that the central bank's control over the price level is at best partial and largely unidirectional. The price level is anchored to the wage rate, which monetary policy can readily push up by being too expansive but which it can hardly hope to force down, except possibly through the painful and wasteful route of prolonged and widespread unemployment. Furthermore, if the minimum money wage—the W_0 of equation (5)—tends to be pushed up even before full employment is reached, whether through powerful unions or through partial bottlenecks or both, and if the rise tends to exceed the rate of increase of productivity, then monetary (as well as fiscal) policy will be faced with the unsavory choice between "creeping inflation" and chronic unemployment. Whether this dilemma is in fact a serious and real one revolves around the issue of the determinants of the over-all level of money wages, an issue that the Keynesian analysis has opened up but that is still far from settled. [See INFLATION AND DEFLATION; see also Phillips 1958.]

One other implication of the Keynesian framework, which can be only touched upon in this survey dealing primarily with monetary aspects, is that fiscal policy provides an alternative approach to the control of aggregate demand for economic stabilization [see FISCAL POLICY]. Fiscal policy can be accommodated in our macroeconomic model by adding government expenditure on goods and services as a component of aggregate demand in equation (1'), making consumption (and possibly investment) depend on taxes as well as on income produced, and adding an equation relating tax collection to income and tax rates. Without attempting to pursue this line here we may indicate that, in terms of Figure 4, fiscal policy—defined as policy concerned with the level of government expenditure and taxation—will affect the position and shape of the aggregate demand relation yy . An

increase in expenditure will shift it upward and to the right; an increase in tax rates will shift it in the opposite direction. Thus, given a position of less than full employment equilibrium such as a in Figure 4, output and employment could be raised toward or up to the full-employment level by increased government expenditure, tax reductions, or both, which would shift the yy curve to the right.

The possibility of affecting equilibrium output and employment through fiscal tools becomes of critical importance in the special "Keynesian case," in which the aggregate demand is so depressed that the yy curve intersects ss to the left of the minimum achievable interest rate, r_m . In this case (illustrated by the curve $y'y'$ in Figure 4) full employment, as we have seen, is beyond the reach of monetary policy, for no money curve can have points to the left of r_m . Fiscal policy is then the only effective tool of stabilization policy, at least until the yy curve has been shifted rightward enough to cut ss to the right of r_m .

Beyond this point—and, more generally, whenever the intersection of yy and ss is to the right of r_m —either fiscal or monetary tools can be used in the pursuit of full employment and price stability. Of course, both tools can be used simultaneously and in coordinated fashion. This should be clear from the fact that, in terms of Figure 4, fiscal policy acts basically on yy whereas monetary policy acts basically on the money curve. (The graphical apparatus of Figure 4 was chosen to illustrate the working of the system partly because of its convenience in isolating the *modus operandi* of monetary and fiscal policy.)

There is a substantial literature concerned with the analysis of the relative advantages and shortcomings of monetary and fiscal policy in terms of such criteria as reliability, response delays, ease of implementation, and reversibility (for monetary policy, see Johnson 1962, pp. 365–377; for fiscal policy see, e.g., Keiser 1964, part 5), effects on long-run economic growth (e.g., Smith 1957; Modigliani 1961), and, more recently, differential impact on the balance of payments (e.g., Mundell 1962). Because of the complexity of the problem it is not surprising that there have been substantial differences in points of view between economists favoring the use of one tool, or of some specific mix, and those favoring others. These differences can be traced in part to differences in the subjective valuation of different goals. But in part they revolve around disagreement about the empirical importance of the "Keynesian case" in which monetary policy becomes powerless to maintain or re-establish full employment, either because it is

ineffective in reducing interest rates any further (at least in the short run) or because the achievable reduction in interest rates is insufficient to induce the required expansion in investment and aggregate demand.

Liquidity preference, that is, the proposition that the demand for money is systematically and significantly affected by interest rates, has proved to be a major, lasting contribution to economic analysis, well supported by empirical evidence. From an analytical point of view its great significance lies in the implication that under certain conditions—the "special Keynesian case"—even an economy with flexible wages and prices might not possess a stable full-employment equilibrium. But beyond this fundamental theoretical contribution, the dramatic impact of the *General Theory* on economic theory and policy can be traced to its insightful analysis of the role of liquidity preference in a world of widespread wage and price rigidities. This analysis has led to a new understanding and fundamental reappraisal of the role of money and of the tasks and limitations of monetary and fiscal policy.

With downward wage rigidity (and even ignoring international trade) money cannot be regarded, even in first approximation, as "neutral," a mere veil having no effect on the economy other than the determination of the price level, except possibly when the money supply is excessive. Under conditions of less than full employment due to lack of demand, and barring the special Keynesian case, monetary policy plays a crucial role in the determination of income and employment. In the special Keynesian case, on the other hand, monetary policy breaks down, since it is incapable, at least in the short run, of affecting either output or prices.

LIST, FRIEDRICH

Friedrich List (1789-1846), German economist, was the son of a tanner from the free town of Reutlingen (Württemberg). Early in his life he absorbed the political ideas and doctrines of the Enlightenment, finding in them an excellent weapon against the rule of an arbitrary bureaucracy and the lingering restrictions of the age of the guilds. In the years following the defeat of Napoleon, he was able to give full scope to his liberal political ideas in his capacities as adviser to one of the leading statesmen of Württemberg, as professor of political economy at the University of Tübingen, and as editor of several periodicals.

With the rising tide of German reaction, however, his activity became suspect. When in 1819 he established an association of merchants and industrialists in Frankfurt am Main, the Handels- und Gewerbsverein, and advocated the abolition of internal German customs barriers, the officials of many German-speaking states, and especially Metternich, the Austrian chancellor, began to look upon him as a demagogue. In 1820 he was elected to the legislature of Württemberg. When he petitioned for an extension of local self-government and for publicity in judicial procedure, he was sentenced to ten months' imprisonment for at-

tempting to undermine the stability of public institutions. He fled abroad in 1822 and led a wandering life for some years. In 1824 he returned to Germany and was promptly arrested. Released on the promise that he would emigrate to America—he had been invited by Lafayette—he sailed for New York in 1825.

In the United States, List engaged in various activities. He lived in Pennsylvania, first as an unsuccessful farmer, near Harrisburg, and then as the editor of a German newspaper, *Der Adler*, in Reading. He also discovered and successfully developed an anthracite coal mine near Tamaqua, Pennsylvania; the railroad he built to serve it—known as the Little Schuylkill Navigation Railroad and Canal Co.—was opened in November 1831 and was at the time the only railway line carrying both freight and passengers. At the same time he was a keen observer of the economic and political problems which beset the growing country; his entrepreneurial experiences confirmed his earlier doubts about the universal validity of Adam Smith's doctrines. He concluded that a protective tariff is indispensable for industrially underdeveloped countries. At the suggestion of Charles Ingersoll, vice-president of the Pennsylvania Society for the Promotion of Manufactures and the Mechanic Arts—the leading protectionist organization of the time—List wrote his "Outlines of American Political Economy" (1827). This was his first attempt at a systematic formulation of his views, and, indeed, it was the first attempt of any kind to draft a national system of political economy that was valid for early high capitalism. Copies of the "Outlines" were distributed to members of Congress, and the adoption of the Tariff Bill of 1828 was a direct consequence.

List supported the election campaign of Andrew Jackson in 1832 and was rewarded by being appointed American consul in Germany, serving first in Hamburg and then in Leipzig. While still American consul, he embarked on an ambitious plan to organize a German railway system. He contributed greatly to the development of the line between Leipzig and Dresden in 1837; it was one of the first railways on the Continent. The venture, although successful in itself, proved a source of personal and financial disappointment and even induced him to leave Germany for France.

It was in Paris in 1837 that List wrote his second systematic work, "Le système naturel de l'économie politique," which he submitted to the Académie des Sciences Morales et Politiques. The work was not rediscovered until 1925 and was published for the first time two years later in French and Ger-

man (see *Schriften*, vol. 4). In this work, List deepened and expanded the theoretical system sketched in the "Outlines" and gave it, in addition, a historical basis. But the full results of his far-reaching studies and his international experiences were incorporated only in his best-known work on the subject of political economy, *The National System of Political Economy* (1841), which was written in Paris but appeared after List had finally returned to Germany in 1840. Beginning in 1843 he published *Das Zollvereinsblatt*, an influential review devoted to the dissemination of his ideas, which were by then both supported and confirmed by the rise of industrialism. He began to exercise an important influence on public opinion in Germany. However, financial worries, combined with the failure of his plan for an alliance between Germany and Great Britain, drove him to despair and led to his suicide.

In the nineteenth century List was the only economist, other than Karl Marx, who strongly emphasized the close interrelation of economic theory and political factors. He believed that economic doctrines have no abstract validity; he always examined accepted economic views and developed his own ideas in terms of concrete political areas at definite levels of economic development. He severely criticized the classical writers for not being aware of the great social and economic significance of the nation. For List, the nation is the most important link between the individual and mankind, whereas the economic principles of the classical school reflect the industrial and commercial supremacy of England in the nineteenth century and are inapplicable to the needs of underdeveloped but rising countries, such as nineteenth-century Germany, France, and the United States. Observing the destructive consequences of cheap British exports to the numerous small German states—consequences of the application of the English free-trade theory—List developed his countertheory of productive forces and of economic stages, related both to historical and cultural contexts. This was the basis of his later efforts to foster, by the development of railway systems, etc., the economic integration and industrial growth of the different German states that had been organized into the Zollverein (Customs Union) in 1834.

List's theory of protectionism, as presented in *The National System*, was actually only a small part of a much larger system in which he intended to deal with agricultural theory, the concept of balance between agriculture and industry within any economy, and the significance of the internal market. Unfortunately, his ideas were often not suffi-

ciently clear, and his arguments were not always sound—the theoretical element in his basically historical approach was not adequate to the task he set himself. Consequently, his writings were often misunderstood. In the controversy over free trade, for example, some stressed List's argument that infant industries need protection if the nation's productive forces are to be developed, while others realized that free trade was List's ultimate goal. No one seemed to understand, however, that neither argument was central to List's concern. Rather, he wished to demonstrate that the growth of an economy is an organic process and that it is only because growth is organic that every nation has a temporary need for protection. Thus, List denied that the policy prescriptions of classical economic theory are absolute and asserted that a nation's best economic and commercial policy depends on its actual stage of development. The advisability of free trade is, therefore, a matter of politics and is not subject to a quasi-religious belief, as it was for the classical economists and as it is even today for many "neoliberals."

List's theory of economic stages is related to the pervasive eighteenth-century concept of harmony, for it is harmonic development that he saw realized in the *Normalnation*, the state of national development when productive forces are completely utilized. The fact that evolution proceeds from primitive conditions to the agricultural state, then to the agricultural-and-manufacturing state, and finally to the agricultural-manufacturing-and-commercial state may not only stimulate effort in underdeveloped nations but, if correctly interpreted, may also warn them against the dangers of underestimating the importance of agriculture and overestimating that of the most modern type of industry.

List was opposed to the individualistic-cosmopolitan orientation of classical economics, with its focus on value theory. He defended his organic doctrine of productive forces against the classical atomistic-materialistic approach, and he upheld his own concept of the cooperative aspects of the productive process against the classical stress on the division of labor. His dynamic approach and his consequent interest in the development of productive forces led him to his belief in the value of protective tariffs as a method whereby underdeveloped countries may exploit their natural resources and raise their economic level.

List's "Blicke in die Zukunft" (1846a), his vision of the political future, also manifests his concern for harmonic balance. He believed that the legal system of a developing nation should be preserved

as a cultural prerequisite, as an ethical standard, and as a framework for political action both by individuals and by the people as a whole. Thus, the man who pioneered the Zollverein and heralded the politico-economic unity of the German nation had enough insight to anticipate the need to set limits to a possible German rise. Much more farsighted than other political thinkers of his time, he predicted the inevitable division of the world into a few mighty empires. He foresaw the enormous growth of American population, industry, and power in the twentieth century, and he even anticipated the great impetus that Russia's "conditions of culture, constitution, law and administration" would need in order for her to become a world power. He therefore consumed his last energies in fighting—without mandate or title—for an Anglo-German alliance. Such an alliance with a united Germany would preserve England's hegemony and would save Europe from being crushed politically between the two rising world powers, Russia and the United States.

For a hundred years List's system was generally accepted without really being understood, even in Germany. Free traders, for example, thought he was a reactionary, although he was the founder of the movement that consolidated Germany commercially and that eventually destroyed more custom-houses and more obstacles to trade than were swept away by the political whirlwinds of the American and French revolutions. The efforts to integrate Europe in the years after World War II, however, led to a reappraisal of his statement: "Commercial union and political union are twins; the one cannot come to birth without the other following" ([1846b] 1931, p. 276). Many passages in *The National System* can be easily adapted to the post-World War II situation by changing only the names of the states. It is even possible to maintain that List foresaw, strove for, and advocated a European common market; the German economic and political union of the nineteenth century was simply a preliminary stage.

Since World War II the Anglo-Saxon world has also become interested in the ideas that concerned List. Streeten (1959), for example, has stated that in *The National System* List clearly formulated the now widely discussed problem of "balanced growth" in underdeveloped countries. It is also recognized that List was one of the first economists to emphasize the importance of so-called social overhead capital (especially the means of transportation) as a necessary precondition for any economic development, be it in Germany in the nineteenth century or in the many underdeveloped countries of

the world in the twentieth. Paul Samuelson (1960) has even placed List among the really important American economists, not only because he began formulating his theory of economic development during his stay in the United States but also because—like the majority of American economists of the past—he can be characterized by a protectionist tendency and a nationalist attitude. Thus, for the practical questions of the integration of Europe and the industrialization of underdeveloped countries, List's work remains of utmost importance, while as a theorist, he is significant as the originator of the historical theory of economic growth.

LITERACY

Whenever the term "literacy" is used, a context is always implied. If the context is archeological, anthropological, or ethnographic, literacy usually refers to the cultural fact that writing has been invented and that the society contains a class, a caste, or an occupational group whose members keep accounts or preserve religious and moral precepts in written form or use writing for some other specific purpose. So used, literacy implies also the contrasting idea of *preliteracy*—a cultural stage in which writing has not yet been invented. The change from preliteracy to literacy—the spread of literate societies throughout the world—probably began in ancient Sumer during the fourth millennium B.C., through a gradual transition from pictography to the use of an alphabet.

If literacy is used in a historical or modern comparative context, then the implied contrast is with *illiteracy*. Literacy then refers to the degree of dissemination among a society's population of the dual skills of reading and writing. Here a "literate" society is one in which most adult members can

read and write at least a simple message. In this context, England, the United States, Sweden, Denmark, the U.S.S.R., and Japan are among the literate societies, whereas Iraq, Haiti, and Nigeria, for example, can be called illiterate—or, at least, not yet literate—societies, even though they contain many highly educated persons.

Extent of literacy

As the great variation between countries with respect to illiteracy (Table 1) has become better known, concern about its consequences has greatly increased. For some, the existence of high levels of illiteracy detracts from the dignity of man and constitutes evidence of immense numbers of personal tragedies for the illiterate adults who are thereby prevented from escaping poverty and mental isolation. To others, illiteracy is primarily an obstacle to

peaceful and friendly international relations and to democratic processes within countries. Still others are aware that low levels of literacy act as brakes on the advance of countries along the paths of social and economic development and political power. These concerns have brought on a variety of efforts to gather detailed information on the extent of literacy in the world's countries and on the conditions under which the diffusion of literacy takes place.

From a world perspective, it is evident that in 1950, the latest date for which world-wide estimates are available, some 53 per cent of the world's population aged 10 and over were able to read and write a simple sentence; that is, in 1950 there were at least 800 million illiterates above the age of 10. The dissemination of literacy skills that has taken place since then is unlikely to have raised the per-

Table 1 — Illiteracy in selected census countries, by continent^a

a. The reader is cautioned against insisting too closely on comparisons between countries whose literacy rates fall within the same decile range. Moreover, rates taken from international sources such as UNESCO (1957) are not always identical with rates calculated from statistical compendia, because persons whose ages are unknown may be omitted or included in the age group 10 and over.

b. Only countries with rates above 10 per cent about 1950 have been included.

c. Population aged 15 and over.

d. Population aged 6 and over.

e. Data for 252 towns only, based on a 20 per cent sample; population aged 16 and over.

f. Population aged 5 and over.

Sources: Calculated from official data (census, statistical compendia, etc.) for each country, or from international sources such as UNESCO 1957 and Demographic Yearbook 1960, pp. 434 ff.

Table 2 — Illiteracy in the major world regions, 1930 and 1950, and in developed and under-developed countries, 1950

	PER CENT ILLITERATE OF ALL PERSONS AGED 10 AND OVER ^a

Middle America	59	48	22	53
Asia	81	70	2	75
Africa	88	88	56	91

a. The figures given in this table represent the weighted average obtained by combining the official and estimated rates for all the countries within the geographical division.

b. Developed countries are those with less than 50 per cent of their economically active males in agricultural pursuits, including hunting, fishing, and forestry; underdeveloped countries are those with 50 per cent or more of their economically active males in these pursuits. For a rationale of this division, see Davis (1951b, p. 8).

c. Abel and Bond (1929, p. 51) give a world average of 62 per cent for around 1920

Sources: For 1930 Davis 1948, p. 614; for 1950 revisions have been made of Golden 1955, p. 2; for another set of 1930 estimates, see UNESCO 1957, p. 15.

centage to 60 or to have decreased the number of illiterates very much below 800 million, since population has grown very rapidly in this period. But, as Table 2 shows, the 1950 level represented a considerable proportionate gain over 1920 and 1930.

The literacy revolution. The world's transformation from largely illiterate to moderately literate began in the industrial nations of western Europe; the recent gains in world literacy reflect the entrance into this transition of an ever-increasing number of countries in many areas. As Table 1 shows, the differential spread of the literacy transition in 1950 suggests that today's countries can be arranged along a literacy scale that exhibits a definite pattern. The lowest rates exist in those areas that have completed the transition; the highest, in areas such as Ghana, Iraq, or Haiti, in which the transition has hardly begun; and between these two extremes fall all those countries, such as India, Pakistan, Bolivia, Paraguay, Mexico, and the Philippines, which are in the midst of the transformation.

The transformation from preponderantly illiterate to literate in the world's old industrial nations, which was accomplished in about 75 to 100 years, can be documented from official information and from estimates. At the beginning of the nineteenth century, although literacy and schooling were more

general than is often realized (Anderson & Bowman 1965, p. 345), at least half the adult population of England and Wales was illiterate, in 1850 the proportion had probably dropped to about 45 per cent. By 1910 illiteracy had been largely eliminated, with perhaps 5 per cent of the adults still illiterate and these concentrated in the older age groups; in 1914 0.8 per cent of the men and 1.0 per cent of the women signed the marriage register by mark (for all these estimates, see UNESCO 1957, pp. 177 ff.).

The decline of illiteracy in countries entering the literacy transition later can be shown by information for the U.S.S.R., Italy, and Greece. In Russia illiteracy declined very rapidly—from about 76 per cent in 1897, according to official census figures, to about 2 per cent in the early 1960s in the population aged 9 and over (United Nations, Statistical Office 1963, p. 312). In Italy and Greece the transition has been slower. In Italy, illiteracy among marriage registrants declined from 65.8 per cent in 1872 to 3.3 per cent in 1951 (UNESCO 1957, p. 169); illiteracy among persons 10 and over fell from 75 per cent, according to the 1861 census, to about 8 per cent, according to the 1961 census. In Greece illiteracy in the population aged 8 years and over declined from 60 per cent in 1907 to about 25 per cent in 1951 (UNESCO 1957, p. 90).

Because the world's transformation from illiterate to moderately literate had its start in the West and has been completed primarily in the world's urban-industrial countries, these nations have a disproportionate share of the world's literate population (Table 2). In some major areas of the world, such as India, Pakistan, and Egypt, the proportion of the adult population that is illiterate is still very high. In India the illiteracy rate for the population aged 10 and over declined from 95 per cent in 1881 to about 70 per cent in 1961, according to the 1961 census (*Demographic Yearbook*, 1964, p. 698). Whereas the decline of illiteracy in Pakistan and Egypt has followed about the same pattern as in India, some areas, such as Haiti, Mozambique, and Ghana (Table 1) have hardly begun the transition. Even the breakdown by continents understates the concentration of the literate population, because within both Asia and Africa the literate population is mainly in a few countries or in cities. For example, in 1950 Japan—the major highly literate nation of Asia exclusive of the U.S.S.R.—had only 6 per cent to 7 per cent of Asia's total population but at least 20 per cent of its adult literates. Future literacy gains for the world as a whole depend, then, very heavily on the degree to which the highly

illiterate countries of the world become involved in this educational transformation.

Evaluating literacy data

Official literacy information can often be obtained from enumerations of total populations (census counts), though sometimes it is based on marriage registers, on tests given to military recruits, or on sample surveys. The results of these enumerations are usually made available in official sources. While minor census inaccuracies can rarely be detected, major inaccuracies in literacy enumeration are discoverable through careful evaluation or by check through independent estimates. For example, because past school enrollment rates for all countries correlate moderately highly with present literacy rates, for a specific country past enrollment rates provide one means of checking the accuracy of census results on literacy.

Definitions of literacy. Census definitions of literacy usually refer to the minimum level of literacy skills; hence they are relatively simple and clear. Yet they still differ slightly from country to country because the instructions to enumerators incorporate somewhat different conceptions of what constitutes the minimum level. In India, for example, government statisticians have instructed enumerators to count as literate only those who have the ability to read and write a simple message in any language, a definition proposed by the United Nations Population Commission. When these instructions are carried out by local school-teachers, few persons are likely to be counted as literate who do not have the minimum skills. In 1930 Finland applied perhaps the strictest minimum definition: only those persons were classified as literate who passed a rather difficult test. Those who failed were divided into two categories, the semiliterates, that is, persons who could read and write but made orthographic errors, and the illiterates, who could neither read nor write (UNESCO 1957, p. 29). By contrast, in the Hong Kong census of 1961 (as in many others) a person who *said* that he was able to read a language was assumed by inference also to be able to write it and was classified as literate. The acceptance of what the enumerator is told may result in inflating the percentage literate or, in some special cases, lowering this percentage (Davis 1951a, p. 151).

Literacy proportions. Because of differences in definition and in enumeration procedure, no actual figure or proportion can be accepted with complete certainty for any area; however, for word-wide comparisons and analyses of literacy, we can prof-

itably use a given proportion as an indicator of the literacy level achieved by a country. The use of literacy proportions as indicators makes it easier to take advantage of literacy proportions available from enumerations of such segments of the population as marriage registrants or recruits. For example, in the 1930s the proportions obtained by each of these enumeration procedures placed France among the highly literate nations of the world (UNESCO 1957, p. 22).

Even when we treat literacy proportions as indicators, it is still desirable to eliminate children from the calculations of rates and to compare rates for the same age groups—preferably 10 and over or 15 and over. Underdeveloped countries frequently have a large proportion of their population under 10 years and cannot manage to teach even the minimum literacy skills until about that age. However, in some cases (see Table 1) it is necessary, for lack of more detailed information, to use the rates for age groups 5 and over, 9 and over, or 15 and over as *estimates* for the age group 10 and over.

Obviously, *illiteracy* rates for the total population, as well as for persons aged 5 and over, are higher than for any of the older age groups; in India, for example, the rate for the total population in 1951 was 83.4 per cent, whereas for the population aged 10 and over it was 80.1 per cent. The rates for the age groups 10 and over and 15 and over are usually quite close; for example, in 1948 in the Philippines the illiteracy rate for each of these age groups was about the same.

For detailed comparisons between two countries, age-group differences and other variations in enumeration results—as in the number of persons returned as “literacy status unknown” or “age status unknown”—must be carefully examined. When literacy proportions are used as indicators, these variations create problems only in rare cases.

Use of estimates. Since some countries have never taken censuses and others have not taken a census for many years, an appraisal of the world's literacy status at one time, 1950, must rely to some extent on estimates. The fact that estimates are used need not imply inaccuracy; some estimates are superior in accuracy to the average census. If, for example, the estimate is derived from reasonably accurate census returns on literacy or from valid statistical noncensus information, or from both, it may be quite reliable. For instance, on the basis of school enrollment information it was estimated that the illiteracy rate for Iraq in 1950 would be 85 per cent of the population aged 10 and

over; the census returns for 1953 showed 89.1 per cent illiterate for the population aged 5 and over, or about 85 per cent for the population aged 10 and over.

China and Indonesia present perhaps the most difficult problems of estimating literacy rates. For China there are no national census figures on illiteracy available, and because of the paucity of other accurate information estimates range from 50–55 per cent illiterate for the population aged 15 and over (UNESCO 1957, pp. 16–17) to 70–75 per cent for the population aged 10 and over (Golden 1955, *passim*). The estimate for Indonesia also requires special comment. The census returns of 1930 gave Indonesia an illiteracy rate of 90 per cent for the population aged 10 and over; this figure is so high that it raises doubts about the official estimate of 39 per cent for the population aged 13 to 45 (United Nations 1963c, p. 15). Other estimates for Indonesia suggest an illiteracy level of 80–85 per cent for persons aged 15 and over (UNESCO 1957, p. 39) and 75–80 per cent for the population aged 10 and over (Golden 1955, *passim*). But despite such occasional anomalies and the general impossibility of absolute exactness, world-wide comparisons and analyses can most usefully be undertaken.

The meaning of literacy figures

The unequal distribution of literacy skills in the world stems from the fact that behind a given level of literacy lies the whole institutional structure of a society, particularly the occupational structure. Hence, the sharp contrasts in literacy levels between developed and underdeveloped countries (see Table 2) reflect the differential spread of industrialism through the world; the slighter differences among countries at about the same level of industrial development indicate other differences in the countries' institutional structure. Transition from illiteracy to literacy for a whole country is accompanied usually by differential rates of transition within the population. Literacy skills are acquired more readily by young adults than by the aged; by those aiming for skilled occupations for themselves or their children; and by those—such as city dwellers—who have relatively easy access to the means of learning. In general, then, throughout the transition some literacy differentials within countries are predictable.

Literacy and economic development. The close connection between the prevalence of literacy skills among the adult population of a society and the nature of the society's occupational skills has been

demonstrated in several ways. In the first place, the invention of writing itself was clearly connected with other changes in human societies, such as increased occupational differentiation and the emergence of the first true cities. In general, the presence or absence of writing has been used as a criterion to distinguish between civilizations and tribal societies. Further, it should be emphasized that no country's adult population became *preponderantly* literate until after the industrial revolution. Statistically, the dissemination of literacy and the changes in the occupational structure in today's industrial nations are very closely linked; the coefficients of correlation for these time series are all above .9, where 1.0 would indicate perfect correspondence (UNESCO 1957, pp. 177 ff.; Golden 1955, p. 3). Indeed, not only is mass literacy a recent phenomenon in any society, but it is still confined to a relatively few countries. For 1950 literacy rates of the countries and territories of the world and indicators of the degree of industrial development correlated better than .8 on a scale, where 1.0 would have indicated perfect correspondence (Golden 1955, p. 3; United Nations 1961, p. 42).

The transformation from an illiterate to a literate society is triggered, so most authors suggest, by pressures exerted on governments, on special groups, and on individuals by the changing conditions accompanying industrialization. But it is not easily achieved; the transition usually has taken at least 75 years, though in some spectacular cases only about 50 years. Some societies have at times diverted large shares of their means toward the diffusion of literacy, and others, small shares; as a result, in 1950 literacy progress in some countries was advanced and in others retarded, as compared with industrial change. For example, in 1950 Brazil and Yugoslavia were about equally developed (if industrial development is measured by the proportion of the male labor force in nonagricultural pursuits), yet Brazil had an illiteracy rate of more than 50 per cent whereas Yugoslavia's rate was only about 25 per cent for the population aged 10 and over. This retardation or advance, so several authors have suggested, can prove to be a handicap or an asset for a country's future economic progress (Davis 1955; Golden 1955; Anderson & Bowman 1965). A government's assessment of its country's educational position requires not only a knowledge of the literacy level achieved but also an evaluation of the literacy position in relation to the level of economic development.

I

THE SOCIOLOGY OF LITERATURE

The sociological approach to literature is by no means an easy one. Like religion, sex, and art, literature is protected by taboos both numerous and powerful. To the cultured mind the study of the writer as a professional man, of the literary work as a means of communication, and of the reader as a consumer of cultural goods is vaguely sacrilegious.

Such a revulsion is all the more surprising, as the concept of literature first appeared to describe a sociocultural fact, not an aesthetic one. In Tertullian's Latin, as well as in eighteenth-century English or French, the word "literature" meant the distinctive culture of those who belonged to the social stratum of the *litterati*, "well-read people." It meant practically nothing else in Dr. Johnson's time and was still sporadically used in that sense as late as the end of the nineteenth century, notably by Sainte-Beuve and William Dean Howells.

Even when the Germans—particularly Lessing—evolved from their analysis of the written products of the human mind the objective notion of *Literatur* as the art of expressing one's thoughts in writing, on the one hand, and as the whole of the works thus produced and published in a definite community, on the other, they never separated the literary phenomenon from its social environment in time or space. For the group which gravitated around the brothers August Wilhelm and Friedrich von Schlegel and their pupil Madame de Staël, literature was, in fact as in value, strongly linked to, and even determined by, the two factors

of *Zeitgeist*, "the spirit of the time," and *Volksgeist*, "the national spirit." Madame de Staël was among the first to use the French word *littérature* in the new sense, in her book *De la littérature considérée dans ses rapports avec les institutions sociales* (1800).

Such a clearly stated doctrine, which ultimately elicited Taine's positivist criticism, also stirred up a romantic reaction whose spokesmen individualized and even divinized what came to be called literary creation, while ignoring or denying the collective aspects of the literary phenomenon. Late romanticism established the still current notion of the divine solitude of the writer in the act of "creating." Alfred de Vigny was the prototype of the poet, throwing his poems into the anonymous crowd like a shipwrecked sailor entrusting a bottle carrying his message to the shoreless sea, or escaping the bondage of society by self-destruction.

In fact, social consciousness and a sense of solitude often coexisted in the literary attitude of the nineteenth century, but the contradiction between them was not obvious to the romantics, some of the greatest of whom—such as Byron and Hugo—were keenly aware of their moral solitude yet never ignored the strong ties which united them with society. Nevertheless, literary criticism more and more shifted its emphasis from a collective to an individual outlook. Carlyle, in 1840, did stress the effects of literary reputation on a writer, but his representation of the man of letters as a hero can be considered the turning point of the movement from presociological to psychological criticism. Although William Hazlitt, in the 1820s, tried to recapture the "spirit" of the great literary ages, Sainte-Beuve and after him Matthew Arnold, in the second half of the nineteenth century, strove to reconstruct the personality of writers as perceived through their works.

Meanwhile, in Germany the new science of philology had awakened an interest in form and style which eventually opened a new approach to literature through the aesthetic analysis of the work of art. In the early twentieth century, Wilhelm Dilthey concretized this tendency into a doctrine which gave birth to a strong antisociological current which reigned almost unchallenged in many countries under the various shapes of formalism, *Stilforschung*, and aesthetic structuralism. France, however, remained steadfastly committed to the historical positivism of Taine.

Early attempts

Sociology long avoided the difficult job of analyzing literature. When sociologists—most of them

with a philosophical, not a literary turn of mind—touched on the subject, they included it in the wider categories of art, leisure, or communication, thus ignoring the specific characteristics of literature. Even Marx and Engels were extremely prudent in their handling of literary problems. Plekhanov, who was the first to offer a Marxist and a sociological theory of art (1899), did not treat literature satisfactorily.

There was a sociological tradition in Russian literary criticism. It was handed down from Belinski, a contemporary of Carlyle, through Pisarev, a contemporary of Taine, to the antiformalist critics of the Soviet era. But this "civic criticism," as it was called, merely rested on the assumption that a book must be judged by its revolutionary efficacy and by the degree of fidelity with which it represented historical reality. Most Marxists nowadays think this view much too simplistic to account for the complex nature of the literary phenomenon.

A true sociology of literature appeared only when literary critics and historians, starting from literature as a specific reality, tried to answer sociological questions by using current sociological methods. The difficulty was to formulate the questions. By the time an interest in sociology was awakened among literary specialists the habit had been formed of working on the writer as an individual or on the literary work as an isolated phenomenon but seldom on their relationship to the reading public.

As early as 1931 the German L. L. Schücking had tried to give an outline of a sociology of literary taste, but his attempt found little response. On the other hand, when the Hungarian György Lukács, after his conversion to a rather personal brand of Marxism, tried to base a method of critical analysis on a parallelism between the aesthetic patterns of the work of art and the contemporary economic structures of society, he certainly initiated a new type of sociological investigation in literary criticism (1961). The Lukácsian sociology of literature is widely followed in eastern and western Europe, particularly in France, where Lucien Goldmann may be said to have brought it to a high point of effectiveness (1950; 1964). It opened wide and numerous vistas on the social nature of literature, and no further studies on the subject can ignore it. Yet, although Lukács and his followers take into account society as the reality behind the appearances of literature, they still consider the work of art as an end in itself and neglect the part of the reader in literary communication. Indeed, they as much as ignore the very notion of literary communication.

Literary communication

Early sociological investigation in literature was stalemated by the antinomy between the ontological and phenomenological conceptions of literary criticism. Only when existentialism threw a new light on things was it possible to achieve a breakthrough. In that respect Jean-Paul Sartre's essay *What Is Literature?* (1948) may be considered a landmark. Sartre's idea, ostensibly very simple, was that the literary work—that is, the written product of the mind—only exists as such when it is read, since writing without reading is nonsense. An unread book is nothing but a handful of soiled paper. From this premise the inference is that the literary phenomenon cannot be the work of art itself, but rather the meeting and sometimes the clashing of two free acts, one of production and the other of consumption, with all their effects and side effects on moral and social relations. There is always another man in literature: a writer for a reader and a reader for a writer.

In fact, no fully satisfactory result may be obtained in investigating literature with sociological methods if one does not start from a clear idea of what in literary phenomena is fundamentally social.

There is danger in submitting the written product of the mind to purely aesthetic criteria. Although literature is an art, it is an impure one precisely because its main tools are language and writing. Whatever the aesthetic merits of a book may be, the sole fact that it is made up of words and letters—that is, of conventional symbols understood only in a given community, loaded with a semantic content and organized according to syntactic rules valid only for a definite body of population—provides it with an intellectual link to its society which far surpasses in strength if not in scope the links created by the purely sensuous, so-called language of art. The very nature of artistic values is thus inseparable from their actual or potential perception by a public. Instead of limiting the literary phenomenon to the isolated literary work, one should view it as an exchange between a writer and a reader through the medium of a book. Here again we find the familiar pattern of communication. But this pattern alone is insufficient for the needed sociological investigation.

As an instrument of communication the book does not work in a linear fashion. It does not go from one individual to another like a letter. The book appeared in the first millennium B.C., when new materials were found which were light enough to be carried about and smooth enough to allow

quick and easy copying. However it is manufactured, a book is always defined by its two specific functions: multiplication and spatial dissemination of the written word. Although in some exceptional cases a book may have had only one reader, the mere fact that it *was* a book gave it an unlimited potential public. The writer may or may not imagine that public, which in turn may or may not be conscious of its own existence. We already know that the original notion of *litteratura* appeared in ancient Rome as a social characteristic when a highly educated reading public concentrated in a small area formed a community big enough to allow group consciousness. It fell into disuse at the beginning of the nineteenth century when many widely dispersed readers in all strata of society were unable to take stock of themselves as a community.

The literary milieu. Even in mass society the *litterati* of each ethnic, national, or social community still retain their group consciousness. Whether it is a motley and fast-changing *monde littéraire* as in France, a bright and sophisticated elite as in the United States, a pauperized intellectual aristocracy as in Spain, or a tight-knit union of writers or academy as in socialist countries, there is always a literary milieu in which ideas are exchanged, judgments passed, and values discussed.

The existence of such a milieu, the breeding ground of literary opinion, is and always has been inseparable from the very fact of literature. Other milieus are, of course, also touched by the literary work, but only the literary milieu has at its disposal the mental and verbal equipment, as well as the means of communication and expression, indispensable for fruitful and articulate intercourse.

In most cases the writer, who is also a reader, belongs to the literary milieu and takes part in the exchange of ideas and judgments. Even in the few cases when he lives apart from the literary world or belongs to an altogether different social set, he cannot escape being aware of the response of the literary milieu to his works and being influenced by it. Few writers are able to refrain from reading the reviews of their books, and those who do cannot ignore the reactions of their publishers, who in their turn are affected by literary opinion.

We are thus led to conceive of literature as a two-way communication in which an original message is broadcast by the writer to a community of readers, whose response to him takes the shape of thoughts, words, acts, and other messages, which react on one another and on the writer himself.

The pattern is made still more complicated by the fact that in normal circumstances many such messages are passed simultaneously to and fro and interfere with one another, while unsuspected readers or communities of readers beyond the social, educational, linguistic, or national borders may catch the message and unexpectedly add their own distortions to the jumble.

Last but not least, the literary milieu being part of a broader society and the writer being also a citizen, the whole network of literary intercourse is subject to all the conditions imposed by social life. In fact the amplitude, the significance, the richness—in short, the human worth—of literature depends to a large extent on the place occupied by the literary milieu and consequently by the writers in the society concerned, on their awareness of their situation, and on the assumption of the responsibilities implied by it. It was such a consideration which led Jean-Paul Sartre to make *engagement* the basis of all literary values.

Literary recognition and opinion

Since the writer exists as such only in the eyes of a reading community, the first problem to solve is that of recognition—that is, who is considered to be a writer by the reading public. The problem is easily understood from the following figures. If we count the names of all the writers retained by the historical memory of a given nation—that is, the writers mentioned in the histories of literature, the encyclopedias, the school or university curricula, the academic theses, the erudite articles published in specialized reviews, the papers read in symposia and congresses—we find that they represent about 1 per cent of the number who actually wrote and published literary books. (For example, in France between 1500 and 1900 about 1,000 out of 100,000 were remembered).

The severity of this elimination has been confirmed by the American psychologist Harvey C. Lehman, who conducted a poll among educated circles in the United States to find out which were the books of recognized importance. Out of the 733 "best books" by 488 authors named, Lehman found 337 books by 203 deceased authors and 396 books by 285 living authors (Lehman 1937). Many similar experiments have been conducted, and they all point to the fact that the historical image of literature in a given community includes a roughly equal number of contemporary and past writers. This means that the production of the more than 30 years which may be considered contemporary balances what remains of the production of several centuries. Furthermore, according

to the findings of the Centre de Sociologie des Faits Littéraires in Bordeaux, France, 90 per cent of the books are eliminated after 1 year and 99 per cent after 20 years. Similar conclusions may be reached through a study of reprints (Schulz [1952] 1960, pp. 104–105).

How, by whom, and according to what criteria is the selection made? A certain amount of contemporary literary recognition is of course necessary. In spite of persistent legends, no book was ever reclaimed after *total* failure at its first appearance. Yet, immediate success is by no means a guarantee of survival. A best seller may be forgotten within a year and a low-sale book remembered for centuries. The picture of a given literature revealed by the contemporary comments of past critics is quite different from the historical picture later presented at school; all students of literature have been told time and again of the instances of "bad taste" displayed by their forefathers.

Education plays an important part in the selection. For example, a survey of French army recruits (Institut . . . 1966) showed that the type of education determines the choice of "noteworthy" authors. French elementary education, with its republican and rationalistic traditions, strongly stresses the eighteenth century, while high school education, with its more bourgeois and conservative leanings, gives the seventeenth century a predominant position. In all cases the number of contemporary and past writers is fairly equal. However, the choices of the recruits with a low educational level were largely stereotyped: their choice of past authors reflected school memories; their choice of present authors bore the stamp of modern mass media. In contrast the choices of the university students were widely differentiated. Moreover, the higher the level of education, the narrower the chronological gap between past and contemporary authors. While in the case of nearly illiterate recruits there may be a "no man's land" of fifty years between the last of the deceased and the first of the living authors, in the case of highly educated recruits there is no gap, but rather a continuously increasing number of choices.

The opinion-leading group is not simply defined by education and social status; age is also important. Lehman (1945) showed that 40 is a critical age for the literary survival of a writer: works published after a writer reaches 40 are more easily forgotten than those published before. The reason is that most writers are recognized as such between the ages of 20 and 30 by readers belonging to a similar age group. This is the average recog-

nitition age for novelists. It may come earlier for lyric poets, and it always comes later for philosophers, a fact which leads to the delusion that poets are short-lived and philosophers hard to kill. In any case a writer seldom changes the clientele which ensured his initial success. The age group which first recognized him carries him along his career and offers him a support in literary opinion until shortly after the group reaches 40, and its influence is superseded by that of younger and more numerous readers. Therefore, about fifteen years after recognition all writers have an appointment with oblivion unless, as sometimes happens, they are taken up by the new opinion leaders and start a career afresh.

Another element which determines the composition of the opinion-leading group is the existence of social and political structures that limit literary exchange. Social stratification is a permanent structure of this type. A society in which the bulk of production is regulated by the demands of a moneyed minority is characterized by a very narrow opinion-leading group, which imposes its taste in wholesale fashion on the masses. The phenomenon is less perceptible in literature than in *haute couture* or in gastronomy, for instance, because reading is a more serious occupation than designing clothing or preparing food and the hold of the higher classes on it is less strong. But the moneyed minority delegates its powers to the hybrid stratum of the intellectuals who in fact belong to the working class but live—at least culturally—on the same level as the wealthy.

Class structure and political structure are, of course, strongly linked to one another, and the state imposes even more demanding limits on literary exchange than does the stratification system. A calculation based on the average age of writers in France (Escarpit 1965, pp. 27-29) shows that the rhythm of the literary generations (Peyre 1948) is determined by the succession of the various regimes in that country. Great reigns like that of Louis XIV in France or Elizabeth I or Victoria in Great Britain and new political eras like those which began in 1792 for France, in 1865 for the United States, and in 1871 for Germany are always marked by the establishment of a powerful and comparatively young (25 to 35) team of writers. This team expresses the national literature and blocks the way to fresh recognitions until it in turn is eliminated by age or by a new historical change.

Political influence is also exerted through the existence of national borders, which partition literary life by erecting various obstacles to the free

flow of books. However, a customs barrier, although its role must not be minimized, seems nowadays to be one of the least insurmountable obstacles. Furthermore, national markets tend to expand, and some countries like the Netherlands have a foreign book market quite disproportionate to their actual literary production: in 1961 it was equal to that of France or West Germany. Yet even internationally we find an opinion-leading minority based on economic power. The United Kingdom and the United States, with their huge industrial and financial machines and their almost universal language, account for nearly two-thirds of the Western book market. On the other hand, they import few books and translate still fewer, being practically self-sufficient (Escarpit 1965).

For most other countries language is a more effective barrier than customs. The 1,200 million potential readers in the world (probably no more than 200 to 300 million of whom are habitual readers) are distributed in more than a hundred linguistic enclosures. Yet five languages (English, Russian, Spanish, German, and French) account for 75 per cent of the world book production and 40 per cent of the readers. All the other language units suffer either from a scarcity of readers or from a scarcity of writers (the case of Communist China is passed over for want of verified data). Translation in its present form and organization is not adequate to remedy this disparity, since much fewer than 10 per cent of the books published in the world are translated into another language and nearly 75 per cent of these come from English, Russian, French, and German.

In sum, the minority responsible for the literary recognition of writers and for the elaboration of literary opinion can be defined as the university-educated intellectuals belonging to the influential circles (moneyed class, "upper crust," high political or technical strata) of the five highly developed economic powers with an important mass of population and a widely spread language: the United States, the United Kingdom, the Soviet Union, Germany, and France—a bare ten or fifteen million people.

Literature in mass civilization

The above may seem a pessimistic view and a difficult one to reconcile with contemporary mass culture.

The problem is not really new even if its dimensions are. Several times in the history of written culture the book, as well as the literature it spread, went through sudden mutations, under the pressure of fresh masses of readers. With the spread

of Christian culture, the book evolved from the connoisseurs' *volumen* of ancient Rome to the easily handled *codex*; then to the hand-printed book when a comparatively well-educated urban upper class enjoyed enough leisure to afford the already flourishing bookseller a commercially workable field; then to the machine-printed hardbound volume of the nineteenth century, when the triumph of the bourgeoisie and the establishment of the capitalist system allowed the creation of an actual market for cultural productions; and finally, in our own time, to the paperback.

The scale of readership changed from the hundred to the thousand, from the hundred thousand to the million. But the change was qualitative as well as quantitative. At each stage, the form of the book met the specific demand of the leading minority and was conceived for one definite type of literature. All the rest—that is, the actual cultural material consumed by the masses of people—was considered as despicable subliterate until the pressure of social changes brought about a shift in the opinion-leading group. This shift was both cause and effect of each technical mutation of the book and led to total revisions of literary values.

In the eyes of the Latin-reading clerk of the Middle Ages the chivalric tales written in the vulgar Romance language (hence the word "romance") were frivolous and meaningless subliterate, but those tales were transformed into legitimate, even noble, literature when printing shifted the responsibility of literary opinion to the urban upper class. The same happened to the novel; despised as "female reading" at the beginning of the eighteenth century, it became the absolute sovereign of literature in the nineteenth, when mechanized printing allowed editions of 100,000 copies for the triumphant middle class, as against the average 2,000 or 3,000 copies of the previous century.

Marginal reading material for the consumption of the masses has always existed side by side with official literature. Long made up of broadsheets, almanacs, and chapbooks disseminated by itinerant storytellers and hawkers, it now takes the shape of illustrated magazines, comics, and photonovels. This literature must not be underestimated, since great works originate in it when it is accepted by the officialdom of a new literary milieu, but it lacks the essential of literary communication: the feedback from the reader to the writer through the medium of the literary milieu.

This feedback is normally ensured not only by the diffuse crosscurrents existing in the literary milieu but by a network of specific institutions,

among which literary criticism and book selling are predominant.

There is no such thing as literary criticism for popular literature like comics now or chapbooks in past centuries. Even when the popular paperbacks are devoted to the publication of recognized works the professional critics hesitate to review them, a fact often lamented by publishers. The literary critic serves less as a guide than as a voice of the cultured public's taste. He is, so to speak, a sample of the literary milieu. His judgments may reflect a great variety of aesthetic, political, or religious opinions, but they all bear testimony to a particular culture and way of life.

In the case of the bookseller one must distinguish the real bookshops, characterized by an autonomous commercial policy based principally on the sale of books, from the mere book outlets, exercising little or no responsibility in the choice of literary goods offered for sale. These outlets may range from newspaper stands to specialized departments in general or chain stores or even huge "book cafeterias."

The part played by the true bookseller in literary communication is an important one. He has to make a responsible choice from the overwhelming literary production. The wrong choices could dangerously burden his stock and clutter up his window, since after one year 90 per cent of what is produced is unsalable. The choices he makes for his stock are influenced by his current sales to all kinds of occasional customers, but those he makes for his window reflect the cultural image that his opinion-leading clientele has of itself. The greater the discrepancy between the composition of the stock and the contents of the window, the higher the efficiency of the bookseller as an intermediary in literary communication, but the narrower his field of influence (Escarpit & Robine 1963).

At ordinary points of sale there is practically no difference between the stock and the window, and the salesman transmits no response from the people who buy reading material in his shop. Such is the case in most places where books are sold. Surveys on the topography of book distribution show that bookshops selling quality books in a responsible way are concentrated in districts of the cities which are rarely visited by working people, at least during business hours.

A commercial policy in the majority of sales points cannot therefore be based on an awareness of the readers' reactions. Books are sold like any other industrial product. Their contents, as well as their presentations, are elaborated according to proved specifications—some of them age-old—

simply enhanced or glamorized by modern techniques. Analysis shows that the difference between the almanacs of past centuries and contemporary magazines lies mainly in language, paper, printing, color, and advertising; the contents—a mixture of horoscopes, amusements, sentimental stories, and recipes—are practically unchanged.

The publisher of mass-circulation books is thus confronted with a difficult problem. "Creative" publishing demands that he make numerous and necessarily hazardous experiments, offering the output of new talents to a responsive public. Yet he must, in view of the substantial capital involved, reduce the risks of his operation either by limiting the experimental field to the cultured elite or by abandoning the idea of "creative" publishing and strictly programming his production—that is, making it conform to the functional needs of a pre-selected mass market.

The latter solution leads to the exclusive publication either of semitechnical works like cookbooks and "do-it-yourself" manuals or of stereotyped reading matter ranging from the lowest kind of sub-literature—comics, photostories—to mechanically produced biographies and historical novels based on standard popular themes.

The former solution may seem more constructive, but it has a twofold drawback. The stock of time-proved classics to be reprinted is not inexhaustible—a few thousand at most—and the supply of contemporary best sellers that can be successfully tried out in the cultured network is very limited. Furthermore, these best sellers have been recognized as such by a public socially and culturally different from the mass public, and this leads to an imposition of literary values from without; a situation quite contrary to a real literary exchange. Such a "bestowed" literature is doomed either to intellectual sclerosis or to the paralyzing conventionality of officialdom.

The mass-distribution book (paperback, *livre de poche*, *Taschenbuch*, etc.) affords the technical means of a fresh mutation of the book as a means of cultural communication. Based on a combination of mass production and industrial design, it makes possible a substantial reduction of price, combined with a convenient size, a pleasant appearance, and quality contents. The principle was first successfully applied by Allen Lane when, in 1935, he founded the British Penguin series. During World War II the need to supply the widely scattered Allied forces with handy and cheap reading material accelerated the diffusion of the paperback, which by 1950 had spread all over the world, upsetting the traditional patterns of publishing. In

the United States the revolution was particularly spectacular. In the 1940s a sale of over 100,000 copies for a single title was considered exceptional, while twenty years later several paperbacks sold well over a million copies a year.

Yet the paperback is nothing but a tool. It cannot solve all problems, and indeed it may raise some fresh ones. As a tool, it is useless and might even become dangerous unless attention is paid to the reactions and needs of the reading public.

The sociology of reading

No sociology of literature is therefore possible without a sociology of reading and of cultural consumption in general. Much has been done in that direction since Schücking's pioneer work on the sociology of literary taste. Such men as R. D. Altick (1957) opened the way to a historical field of investigation which is now widely explored. On the other hand, methods for the study of reading, *in vivo* so to speak, were borrowed from economics by P. Meyer-Dohm (1957) and from the sociology of leisure by J. Dumazedier and J. Hassenforder (1963).

Although the consumption of drama is quite different from that of the book, John Lough's studies of early theater audiences (1957) and J. Duviols' later and more complete work (1965) are also relevant to the sociology of reading.

The main obstacle to a sociology of reading is that, unlike a theater audience, a reading public is not easily defined. One must not mistake the various social circles concerned about literary work for the mass of actual readers, whose size, composition, coherence, and group consciousness vary with each book.

Any writer, consciously or not, addresses prospective readers when he writes; any publisher directs his publication toward an expected public when he plans the manufacture and distribution of the volume; both the writer and the publisher more or less belong to a milieu of possible readers. Each of those publics plays an essential part in the birth and life of the literary work, although few or none of its members may ever read it. There are, of course, instances of books written for a hundred readers and published in a comparatively narrow milieu of a few thousand persons but ultimately read by millions; however, the opposite case is much more common.

The cases of books reaching unexpected and even unsuspected publics beyond social, national, linguistic, or temporal barriers are becoming more numerous. Of course there must always be an environment of contemporary readers to accept a

book at the outset, but even though the existence of such an environment is indispensable, its size and composition may have nothing to do with those of the wider or later groups which will ultimately ensure the success of the book. Indeed, in most cases the later success of a book is due to causes quite foreign to those of the initial success. While the set of readers which was first responsible for the literary recognition of the work shared the historical and cultural experiences of the writer, spoke the same language, and thought according to similar patterns, groups which have no direct contact with the writer's world have no other recourse than to substitute their own keys for the original ones in order to decode the text which is handed down to them.

In fact, reading any work outside the immediate social or historical vicinity of the writer—and a fortiori reading it in translation—implies a betrayal of the writer's intentions, since absolute fidelity would imply a complete reconstruction of the writer's psychological and social environment, a condition which may be partly and painstakingly fulfilled by scholars, but which is in no way compatible with current literary reading.

We must then admit that a literary work, insofar as it survives its time, is permanently reinterpreted and redigested by various groups of readers. Those synchronic or diachronic layers of meaning which are added to it together form its true historical personality. The literary death of a book occurs when no further interpretation or misinterpretation of it can be given. We are thus led to consider "creative treason" as one of the main keys to the literary phenomenon (Escarpit 1961). By "creative treason" we mean an unconscious or deliberate misconstruction of the author's actual intentions when he wrote the book. This reinterpretation may bring out a latent significance of the work of which the author himself may not have been aware or add an unsuspected meaning that can even replace the original one. The most typical examples are Swift's *Gulliver's Travels* and Defoe's *Robinson Crusoe*, which were originally intended as serious works, with a philosophical message, and are now widely read as children's books.

Obviously many books which had a tremendous but short-lived and localized success were never "betrayed" and died soon. Others, in contrast, starting from a comparatively narrow acceptance, continued for centuries to call up wider, deeper, and stronger responses. The question may be raised whether the likelihood of being betrayed is due to some specific quality of the work and not the audience. Such a surmise is quite plausible and points

to one of the ways in which the sociology of literature might help to found a system of literary values.

Such an objective is still beyond our grasp. We can for the time being only strive toward it along three lines of investigation. The first consists in studying the material conditions of reading so that its place in everyday life is clearly defined. According to the periods considered this may be done by historians or by sociologists. Applied to our time such a study may reveal the relationship of reading to the various forms of mass communication and cultural consumption like cinema, radio, television, records, etc. Another approach, mainly psychological or sociopsychological, tends to identify the various motivations and attitudes of readers according to sex, age, occupation, educational level, social class, IQ, etc. Typical patterns of behavior may thus be traced and linked to the factors that influence them. The third approach is through the study of the language of literary appreciation. A project for an international dictionary of literary terms was begun in 1962 by the International Comparative Literature Association. An effort is also being made—particularly in Bordeaux—to investigate the aesthetic vocabulary used by readers of the working class, in order to grasp the mechanism of literary appreciation among readers whose literary opinion is seldom voiced.

The aims and applications of the sociology of literature thus become clearer. Applied to past periods it may help to evolve a new type of historical criticism more directly linked to economic and social history than traditional formal criticism has been. Sociological criticism will never reveal the intimate nature of literary "creation" or supply a universal and eternal criterion of "beauty," but in spite of often stated ambitions, no criticism of any kind ever did or ever will.

More important still, the sociology of literature applied to contemporary problems may, on the one hand, help the persons or agencies responsible for book policy in the various regions of the world to take stock of the new problems raised by mass civilization and may, on the other hand, help the hitherto ignored masses of readers to gain aesthetic consciousness and claim their part of mankind's cultural heritage. It may ruffle a number of connoisseurs, comfortable in their minority culture, who would prefer to ignore what happens beyond their narrow intellectual circle. It may disturb more seriously and even revolt a number of writers who never wondered whence and whither the wind that blows through them. But no true lover of culture—

reader, critic, or writer—will suffer, in the long run, from a clear-sighted awareness of social realities.

THE PSYCHOLOGY OF LITERATURE

The psychology of literature is an emerging, rather than an established, discipline. We can distinguish three aspects or stages in its development, although these are not sharply defined. First is the insertion of psychological questions and theories into the predominantly aesthetic or historical writing of students of literature. Second is the writing of psychologists who seek to explain and interpret literary works by means of theories and techniques developed in other contexts. Third is the psychological analysis of literature by those who try to adjust their method to the peculiar nature of the subject matter and who hope to make discoveries rather than to impose stock explanations. The present article, inevitably narrow in scope, will be organized loosely around these categories in an effort to sample the writings of the contemporary period.

As one of the most distinctive of human activities, literature would seem to be a natural focus of psychological inquiry. How it is produced, how it affects those who enjoy it, what it reveals concerning the author and his society—these are questions that have occupied major thinkers from early times. Psychology of literature is referred to in standard works on literary criticism, and a recent bibliography of the field lists thousands of relevant titles (Kiell 1963). Yet textbooks of psychology rarely mention either literature or psychology of literature. The paradox is partly explained by the positivistic restrictions of psychology and partly by the elusiveness of literature when approached by science.

Nature of literature. Some conception of literature necessarily precedes scientific study of it. Permanent material documents do exist that can be called repositories of literature, but these docu-

ments are simply a modern device for bringing author and reader together in the literary transaction. At an earlier time, essentially the same transaction took place by oral means, aided by gestures and pantomime and often by instrumental music, and nothing was stored in documents. Human memory and capacity for improvisation sufficed. The modern reader is a step removed from the early pantomime, but only a step. He can still turn the written words into spoken ones, and, if he is artistically sensitive, he is likely to do so. He can also, to some extent, experience the various kinds of imagery intended by the words, and, through the sound and imagery and temporal structure of the composition, participate in moods, attitudes, and values that may have acted as initiating and sustaining forces for the author. According to this view, literature is a process of expression by an author which induces a corresponding process of reception in a reader. The process in the reader is not necessarily equivalent to the process in the author, but it is such as to bind him to the author. Literature exists in that union. The author can, of course, be his own reader. This circular transaction, however, is typically not enough; the impulse of authorship moves toward communication.

Imperfect as this characterization of literature is, a scientific approach must be regulated by some such reflections; and since it appears that the literary process requires the scientific observer to be an intimate part of what he observes, it is evident that the methodological problem is grave.

Psychology in general discourse

The bulk of literary criticism falls in the first of the three categories mentioned above. Much of it does not pretend to be psychological. Some of it, however, consciously employs psychological language and theory to dress up, supplement, or govern the critical discussion. Rare are those works that are deeply imbued with psychology and are still, in the main, appreciative. An example is Bodkin's *Archetypal Patterns in Poetry* (1934). Exploring literature from a Jungian base, this book seeks to locate the meeting ground of author and reader in the universal symbols of the collective unconscious. The theory is not merely decorative; it controls the analysis throughout, although it is in turn controlled by mature literary taste.

The creative process. Lowes, in *The Road to Xanadu* (1927), an examination of Coleridge's vast reading as it contributed to the composition of his poetry, is more concerned with the author's part. The thesis that Lowes favors is that the poetic imagination is a variant of ordinary imagi-

nation, depending on the accumulation of miscellaneous images, the mingling and transformation of these in "the deep well of unconscious cerebration" (Henry James), their recovery in consciousness at the prompting of some stimulus, and their utilization in expression. Lowes's psychology is mainly British associationism. From Coleridge he draws such psychological phrases as "twilight realms of consciousness," "state of nascent existence in the twilight of imagination and just on the vestibule of consciousness," and "the streamy nature of associations, which thinking curbs and rudders." To this source of insight Lowes adds introspections of his own on dream and fantasy, and he acknowledges from personal experience that literary erudition and subliminal associative activity are not enough to produce a masterpiece of poetry. He does not explain the needed additional factor, but he refers to it under the terms "vision" and "will."

Lowes is not quite faithful to the author he admires. He reduces Coleridge's fundamental distinction between imagination and fancy to a mere intensity difference in the imaginative energy and ignores the distinction between primary and secondary imagination. For Coleridge, imagination is creative and esemplastic, making and shaping into organic unity, while fancy can only join together mechanically what imagination supplies. Fancy is thus removed some distance from the living I AM, "of imagination all compact," which stands at the source of all created things, whether universe (primary imagination) or poem (secondary). By the phrase "I AM" Coleridge designates the ultimate principle of God or the human soul. As the I AM of God creates the world, so the I AM of the human soul creates poetry. The poet's creative activity, "This light, this glory, this fair luminous mist, / This beautiful and beauty-making power," to use the words of his ode on "Dejection," is essentially joy, the joy of the soul in its own life. Coleridge's distinctions and the terms in which he makes them are the reaction of a poet to the inadequacy of Hartleian associationism for explaining poetry. In dwelling on association, Lowes, from Coleridge's point of view, would be regressing. From our point of view, Lowes may be seen as moving toward the new "associationism" of Freud, who has equally little room for the Coleridgean I AM but must agree with him that association depends more on recurring similar states of feeling than on ideas (Richards 1934, p. 68 in 1960 edition).

Poetry and dream. In agreement with Coleridge and Freud on the importance of feeling is Prescott,

whose *The Poetic Mind* (1922) is an expansion of his earlier essays on the connection between poetry and dream. Prescott's agreement with Freud must not be overstressed. Like Freud he invokes the unconscious; distinguishes two modes of thought (practical and dreaming); closely identifies poetry with dream; emphasizes unfulfilled desire as the motive for both; makes use of the ideas of condensation, displacement, and projection; and otherwise shows an appreciation of Freudian principles. But, on the other hand, Prescott traces these principles to earlier sources, warns against the sterility of psychological science rigorously applied to literature, and takes particular exception to Freud's basic assumption that there is a latent dream content behind the manifest dream. For Prescott both literature and dream are direct, not cryptogrammic, expressions of the mind. He specifically compares poetic creation to sexual generation or the divine genesis of the universe.

Especially in his chapter on the formation of imaginary characters Prescott emphasizes the power of the mind to create. Fictional characters are held to be autogenous objectifications of the mind's tendencies. Although there are also exogenous characters, these exist in the literary composition because of their congruency with the author's desires. Prescott's emphasis has some relation to Coleridge's theory of the primacy of the I AM. That is, Prescott regards poetic creation as more than the concatenation and blending of ideas, whether in the Hartleian or the Freudian style—which would be what Coleridge calls "fancy"; it involves the vital participation of a real being, even to the extent of passing on to fictional characters a portion of real life. Thus it can happen that "the author divides himself to form characters" (Prescott 1922, p. 201 in 1959 edition).

Author types. One of Prescott's examples for the proposition that an author becomes divided into quasi-independent imaginary characters is the French dramatist François de Curel, studied by Binet. Unfortunately, Prescott does not consider Binet's later study of Paul Hervieu and his further reflections on this problem (Binet 1904).

Binet studied a number of contemporary authors by personal interview, including some formal testing, and by analysis of their lives and works. He attempted to sum up his impressions of the creative process by invoking two opposed mental forces, "imagination" and "critical function," the former tending to embody itself in more or less autonomous personal beings, the latter tending to inhibit or suppress this process. He put authors in three classes with respect to the relative strength of these

tendencies. There are those like de Curel, in whom the critical function is suspended during the period of creative activity and the imagination-produced characters use the writer as an amanuensis or sort of trance medium. There are those like Victorien Sardou, in whom the opposition between the two mental forces continues, but the critical function itself becomes one or more of the autonomous persons, participating in the dramatic dialogue with other persons more charged with the imaginative force. (Perhaps, to use a modern analogy, the case would be like that of a social psychologist serving as a "participant-observer" in some passionate social organization and using the opportunity to undermine the fully engaged members.) Finally, there are those like Hervieu, in whom the critical function remains in control so completely that the imaginary characters never achieve full autonomy, being themselves rather the puppets through which the voice of the master speaks. In all three types, however, according to Binet, the literary work reveals the personality of the producer.

Psychoanalytic explanation

As is evident from the preceding discussion, the psychoanalytic influence has been felt everywhere in the study of literature. A varied collection of essays showing this influence at its best has been edited by Phillips (1957). Yet, as the first shock of Freud's innovations has worn off, it has become apparent that the general theory of an emotional, orectic, unconscious origin of literature was not new and that the distinctive psychoanalytic explanatory apparatus—the Oedipus complex, polymorphous-perverse infantile sexuality, the devious dream work—as employed in the interpretation of individual literary works and their authors has yielded dubious results. Long before Freud, Dowden was explicitly pursuing the aim of deducing Shakespeare's personality from his dramas (1875). The psychoanalytic studies in this genre, in comparison, often seem less judicious. Probably the best is the Ernest Jones study, *Hamlet and Oedipus* (1949), which soberly develops the idea proposed by Freud that Hamlet and his creator could be explained by the Oedipus complex.

The seeming arbitrariness of psychoanalytic explanation stems from Freud's theory of the dream (1900), and, by extension, of literature. The dream is supposed to be a coded message from the unconscious. The code consists of certain stereotyped, universal symbols, plus many individual symbols produced by very complex dreamwork. These individual symbols cannot be decoded accurately without the aid of the dreamer's free associations. It is

a technical fault that in the application of psychoanalysis to literature this theoretical point has often been overlooked, the author's literary "dream" being decoded without benefit of the required associations. But there are other reasons for distrust. For one thing, the Freudian approach at times has an uncomfortable resemblance to the cryptographic approach of the Baconians searching through the plays of Shakespeare for hidden evidence that their candidate, Francis Bacon (Lord Verulam), was the real author.

A more general reason is that literature seems in its basic constitution the very opposite of a cryptogram. Authors on the whole strive to express, not to conceal. It is true, no doubt, that a great literary work is thick with meaning, layer upon layer, and that some layers are more sharply articulated than others; but authors are aware of this and welcome the depth of meaning, in exactly the spirit of an orator who is glad for his voice to take on tremors and intonations that do not seem to be called for by the logic of his argument or the matter-of-factness of his vocabulary. The richness and subtlety of a literary work may elude an ordinary reader, but it is doubtful that such deficiency in sensitivity is to be repaired by imputing conscious or unconscious concealment to the author.

These strictures are not meant to disparage the merit of psychoanalysis as a vivifying influence on the study of literature. Recognition of the depth of literature and its relevance to the concerns of the psychiatrist (and vice versa) cannot be regarded as mistaken. Furthermore, the expansion of outlook engendered by psychoanalysis holds much promise for the future. Too huge for consideration here, but an illustration of the promise, is Jung's study of the Miller fantasies in *Symbols of Transformation* (1912).

Studies concerned with method

Imagery analysis. To those who value simple and sharable method, the pioneer work of Spurgeon in *Shakespeare's Imagery* makes an instant appeal (1935). Definition of an image is difficult, but there can be practical agreement, she thinks, about these "word-pictures" in similes and metaphors, whether contained in a single word (as in "ripeness is all") or spread over a considerable portion of a dramatic scene. Once collected, the images can be classified and counted for the sake of answering various kinds of questions. Thus, she demonstrates that Shakespeare's imagery differs from Marlowe's and Bacon's; and she attempts to draw conclusions as to Shakespeare's favorite haunts (for example, gardens), particular experiences (for example,

noticing an eddy in the Avon below the eighteenth arch of the Old Clopton Bridge), and general character. Undoubtedly, at times she pushes inference too far. For example, from Shakespeare's many references to blushing and other quick emotional changes in fair-skinned faces she concludes that his own face was fair-skinned and of a fresh color. It is questionable whether we have, or can have, principles that fully justify such an argument.

Armstrong has extended Spurgeon's method to the study of image clusters in *Shakespeare's Imagination* (1946). For example, he finds that the images clustering around the goose symbol in many of the plays commonly refer to disease and penal restraint, and somewhat less commonly to music, bitterness, and seasoning. Several such image clusters are studied in detail. There seems to be no doubt that certain images tended to cohere in groups in the dramatist's mind, so strongly indeed that the almost inevitable concatenation often results in surprising turns of thought. Armstrong presses his analysis into (1) hidden images and (2) submerged themes. By the first he means the unspoken image latent in a spoken one (as when reference to wax points to the legend of Icarus); by the second, the adumbration of an understory by the images used in telling the obvious one (as when the Hostess in *Henry IV*, Part II, charges Falstaff with unfaithfulness in terms suggesting the Passion of Christ and the betrayal by Judas). Here he touches on an aspect of method which can hardly be reduced to simple counting and cataloguing. The manifold allusiveness of literature makes for a "thickness" which contrasts with the "thinness" of scientific writing. It is this "thickness" which especially baffles the search for perfectly mechanical procedures. Although Armstrong is convincing at this deeper level of analysis, he does not prescribe the conditions that enable him to be. One condition is obviously possession of the right knowledge, for example, knowledge of the New Testament. Other conditions may be inherently less definable, such as that vague but real thing, literary sensitivity.

Armstrong attempts to state some of the organizing principles of Shakespeare's thought and advances a general theory of imagination. With regard to Shakespeare, he infers that a primitive dualism of the warring opposites of life and death, love and hatred, governs the associations; that the extremely free, rapid, fluent associative activity leads to extraordinary combinations but without loss of organic unity; and that, although the surface of the dramas is relatively bare of religious reference, the depths are often permeated with

imagery that gives religious quality to the whole. With regard to imagination in general, he accepts Freud's scheme of unconscious energies working up from a primitive level through a preconscious censorship to produce conscious elements, but he wishes to add to this a reverse direction of work to explain literary creation. He argues that the creator, in directing his will toward a certain achievement, focuses consciousness on obscure points and thus induces processes below the threshold to respond with a solution. The mid-region of the Freudian preconscious censorship (a phrase that may suggest to strict Freudians a misunderstanding of Freud) becomes for Armstrong a region of selective subconscious association where liberating as well as restricting functions occur. His theory thus tries to overcome a one-sided emphasis on pathogenic defense, repression, and disguise, in order to accommodate the full, open, creative expressiveness of artistic imagination.

Analysis of plot and character. Among American personality theorists, Murray has shown an unusual degree of interest in literature and has made a vital connection between literature and the clinic through his Thematic Apperception Test (TAT). The TAT stimuli (pictures) are used to elicit stories, and these are analyzed as revealing the personality of the storyteller, particularly his unconscious complexes (*Explorations* . . . 1938, esp. pp. 530-545). In an admirably concise paper Murray has drawn the parallel between TAT stories and literary masterpieces, as he argues from evidence that authors are reflected in their productions (1943). [See PROJECTIVE METHODS, article ON THE THEMATIC APPERCEPTION TEST.]

Murray reports that experience with numerous college student subjects in the Harvard Psychological Clinic indicates that the personality revealed by analysis of major characters, repeated plots, etc., in TAT stories is consistent with what can be learned in other ways about an individual; for example, judges can successfully match autobiographies against corresponding TAT stories. He finds that TAT authors range from subjective egocentric to objective sociocentric, the former tending to identify consciously with their story heroes. His most definite examples of subjective egocentrism occurred most frequently among students majoring in English, but none of his TAT subjects exhibited the high degree of subjective egocentrism found in the literary geniuses Melville and Wolfe. From these facts it can be inferred that Melville and Wolfe must reveal themselves at least as fully as the students. Murray thinks that literary material can contain infantile complexes and Jungian

archetypes but notes that such unconscious patterns have their support and fulfillment in objective realities. For example, he finds that the Ishmael or social outcast theme, prominent in Melville and Wolfe, is rooted simultaneously in an infantile sense of rejection by the mother (a complex), in the low status of the literary artist in our culture (a sociological fact), and in a long, continuous development of the rebel or Satan myth in the West (a historical fact). In his opinion, analysis of literary works has general validity for personality study, since objective sociocentric authors also reveal themselves as much as the others, although with less awareness.

McCurdy is another worker with a similar interest in analysis of literature as a mode of personality research, and in a series of papers on various authors and a book on Shakespeare (1953) he has attempted to refine method and reach theoretical conclusions. A brief summary of these studies may be found in his textbook on personality (1961, pp. 413-427). McCurdy is phenomenological in outlook, and he views personality as a changing structure of relations between a self and its objects, particularly person objects; or, in other words, as a dynamic social system constituting a personal world. He is therefore inclined to regard a literary work of imagination as a description of the author's world, or at least a significant portion of it, and in analysis to concentrate on such obvious features as the characters and their interactions. To some extent, analysis of plot and character can be quantitative, and McCurdy has explored the possibilities. For example, in his study of the Brontë novels, he quantified the degree of resemblance between the characters by determining the amount of trait overlap in order to be more precise about types of characters and kinship lines between them. In the Shakespeare study, he arrived at weights to represent the relative importance of the characters by counting their speech lines and utilized these weights in several ways. One analysis led to the discovery that the average relative weights of characters within plays follow a simple exponential formula; and this result, which he also obtained for other authors, seems to point to a basic principle of personality organization. In spite of his interest in quantitative procedures, McCurdy would be the last to deny the validity of an impressionistic approach. In fact, he would insist that quantification must be kept subordinate to a nonmetrical understanding capable of grasping wholes, appreciating qualities, and judging values. His persistent hope has been that the study of personality through literature, while leaving room for quantitative and

even experimental procedures, might encourage psychologists to recognize important realities that cannot easily be measured.

One can foresee an era of computer research in the psychology of literature, as quantitative methods are clarified and large-scale comparative studies are undertaken. The danger in such a stepping-up of quantification is that it may divert attention even more from the unquantifiable fundamentals of literature. That direction of development is relatively easy. What is harder and more essential is to keep near and draw nearer to the delicate, passionate, living processes of literary creation and exchange. If we could somehow bind our scientific energies to this far more difficult task, we might grow toward a richer form of knowing than hitherto achieved. In the meantime, we may at least take note of the great, apparently unremovable diversity of reader reaction to any given piece of literature (Richards 1929) and consider the problem which that poses for scientific consensus.

POLITICAL FICTION

Politics has to do with the public exercise of power; political fiction, with the understanding and appraisal of those who are the subjects or objects of this exercise of power. Some writers of political fiction emphasize understanding, others appraisal. In the first case their work, if successful, approaches scientific theory in its insightful understanding of the dynamics of political power. In the second, mere appraisal without systematic understanding produces polemic or diatribe, which may nevertheless contribute expressively to understanding problems of power.

Fiction, political and nonpolitical

As the line between understanding and judging is often indistinct, so also is the line between fiction that is political and fiction that is not. Ever since political leaders first exercised power over the rest of society, writers have had the elite as subject matter—as Sophocles had in *Antigone*. Ever since ordinary citizens began to exercise overt power, notably during and after the Protestant Reforma-

tion and later the industrial revolution, writers have had the additional task of understanding and judging the public exercise of power by both elite and nonelite. This inherent, reciprocal, ancient relationship between the leader and the led, each as the subject and object of power, had not been clearly stated, let alone understood, before the modern activation of ordinary citizens. The infusion of psychological knowledge into culture, notably starting in the twentieth century with Freud, has made it possible to understand and judge political power with a penetration previously rare. Several bold, and a few successful, fictional efforts have been made in this direction. Some of the bolder and more successful ones are discussed below.

Even fiction that is political only by the vaguest of connections, allegorical or otherwise, has had enormous political impact. A very long and rambling Chinese novel, dating from the fifteenth century or before, *Shui hu chuan* (translated in 1933 by Pearl S. Buck under the title *All Men Are Brothers*), has among its themes brigandage, corruption of kings and princes, and the unending effort of valiant, lawless men to destroy the rich and powerful so that the poor and impotent might live in decency and justice. Even before the 1949 revolution a leading Chinese communist called this medieval novel the first communist writing, and it became a kind of guiding light for the revolutionary leaders during the decades before they got full power.

"Ward No. 6," Anton Chekhov's late-nineteenth-century short story about corruption and inefficiency in a lousy Russian hospital, had profound influence on Lenin, epitomizing for him one of the central justifications for the revolutionary drive for power. Comparable in their influence have been the eighteenth-century satires of Jonathan Swift (the most savage, perhaps, being his *Modest Proposal* for solving the population problem in Ireland by selling yearling Irish children to be served as a delicacy on the tables of English gentlemen) and the portrayals of social stench by Charles Dickens in his novels of poverty in Victorian England and by Victor Hugo in France. Harriet Beecher Stowe's polemical novel on early-nineteenth-century slavery in the American South, *Uncle Tom's Cabin* (1852), was itself a contributing cause of the American Civil War and almost a century later infused some animus into the African drive against colonialism following World War II.

Such polemical social fiction, however strong its influence on the climate of political opinion among elite and nonelite, does not, except by portraying the social context, contribute much to understand-

ing or judging political power. By the same token, some ostensibly political fiction, such as Anthony Trollope's *Phineas Finn* (1869), Émile Zola's *His Excellency* (1876), Edwin O'Connor's *The Last Hurrah* (1956), Allen Drury's *Advise and Consent* (1959), and Vladimir Dudintsev's *Not by Bread Alone* (1956), deals with rather peripheral aspects of power. João Guimarães Rosa's *The Devil to Pay in the Backlands* (1956), a Brazilian novel of backland banditry, is curiously reminiscent of the Chinese *All Men Are Brothers* in its preoccupation with primitive moral courage and the search for some justice in a lawless society.

Such fiction indeed involves political issues like corruption, personal integrity, and courage. But it relates these only peripherally to more central issues involved in the exercise of power. Or it only scratches the surface in areas where Dostoevski, Koestler, Orwell, and Mann have excavated deeply. There are books in running brooks, sermons in stones, and politics in everything, but there is also a continuous running babble of political fiction that signifies next to nothing.

The public exercise of power involves man in his relations with the state—that is, his relations with the government and with the citizenry, the public. These relations always include contact between individuals. The contact between one individual and another involves not only appraisal and understanding of the other individual but also appraisal and understanding of oneself.

The protest against unlimited power

The age-old questions of right and wrong, justice, and choice still endure. In recent decades they have been raised anew, in searching analyses of the individual himself, as the agent who chooses between right and wrong, just and unjust. The age-old rote exhortation to exercise power virtuously has in twentieth-century fiction been succeeded by a maturing comprehension of the intimate relations of one individual with others and with himself. Modern writers have boldly explored paths opened by psychologists of both intuitive and empirical orientation and with such modern knowledge have in effect analyzed ancient Greek and Judaic statements of the problem of political power. In the groping exploration of the nineteenth century the Russian Dostoevski had the Grand Inquisitor say in Spanish Seville that mankind wanted bread rather than liberty—wanted to survive but cared not for freedom. In the mid-twentieth century has come the rather antithetical observation that man and society can be enslaved and destroyed only (as Orwell seems to have said) if man, the social

animal, is reduced to the point where his survival depends on the grace of an omnipotent Big Brother. To Dostoevski's assertion that men choose bread rather than liberty Orwell replies that this is so only in a tyranny and only when both are not available and choice is therefore impossible. As will be discussed, this thesis raises questions about the nature of man himself.

Political fiction typically has been written in protest. It has originated not in abstract considerations of man's nature but in concrete appraisal of his circumstances. The protest, more often than not, has been against the social and political *status quo* and has favored some kind of utopia where the contemporary real and evil society and polity are replaced by the good. But with increasing frequency in the mid-twentieth century, the protest has radically criticized the good society envisioned by utopians. It has extrapolated from current developments to their logical conclusion in the polity that ends politics, when the exercise of power is unlimited and controls every human act. Orwell in 1984 finds the origin of this trend in the development of techniques of power by corrupt civilization. With a far more devastating analysis (which he seems to have abandoned in later writing), William Golding in *Lord of the Flies* (1955) finds it in the human soul, released from the restraints of civilization. Orwell says man is socially corrupted; Golding, in this novel, proclaims that man is innately corrupt. Each book is logical; each is equally incredible in its holistic analysis of political action as the product exclusively of either the environment or the organism. Both 1984 and *Lord of the Flies* have, however, set the focus of attention on the human psyche, the point where determining forces, external and internal, do their work and where choice—if the forces are not altogether determining—is made. And, as will appear later, Golding and others have proffered an explanation that is neither strictly environmental nor strictly organic but both.

The economic class struggle

Most political fiction involves status distinctions between people—differences of superiority and inferiority. In one major tributary of writing the status relation arising from economic inequality dominates the appraisal of political power.

A prototype is Thomas More's sixteenth-century *Utopia* (1516), a work of fiction that lacks two of the three classic ingredients of novels, plot and character, but expatiates on a setting that has since become a shibboleth. In *Utopia* the status distinctions of an England in transition from feudalism

to an open society are eliminated in a classless egalitarianism where virtually everyone enjoys the simplest provision of goods. The few who enjoy a little more do so only in consequence of their feudal but acknowledged exercise of political power, which includes authority not only to maintain order and national defense but also to allocate work. To keep the citizens from becoming accustomed to killing, the slaughter of livestock is done by slaves. People are punished as readily for the intent to commit a crime as for its commission. There are few laws and treaties, men being bound together by love, not words.

Deeply troubled as More was by the misery produced when feudally common pasture lands were enclosed and anti-Catholicism was rampant, his future good society looks like a serene early Christian communism. And it employs supposedly popular coercive measures having the gray-brown drabness and uniformity of the totalitarian slave-labor camps that actually came into being in the twentieth century. The election of top princes by high officials, of high officials by lesser ones, and of lower officials by citizens voting in family units seems more like feudalism stood on its head than like representative democracy. Reacting against the atavism of his time (a breakdown of community and law that seems to occur in all societies in transition), More could propose only a reversion to humanized, equalized, coerced feudalism.

In Émile Zola's *Germinal* (1885) the exploitation theme of More, deriving from English rural poverty, appears in a French industrial setting. The exploiters are not landowners enclosing once-common lands, thereby causing sheep to devour men (as More put it), but mine operators who work their miners to death. One part of the problem is the class system. The other part is the selfishness of man, whether bourgeois or proletarian. Zola abhorred the state of affairs in which the strong devour the weak, in which the lawless aim of each is to acquire power for himself, and in which the ability to love, sexually or otherwise, becomes a means of exploitation. Without resolving the issues of egoism, power, and love, Zola, in Marxist fashion, trusted the power of the proletariat to lay the basis for utopia in the next century by an avenging destruction of the bourgeoisie.

Later novelists have likewise reacted to the class crisis after industrialization, and they have similarly described despair and longed for utopia. The American nineteenth-century Populist Ignatius Donnelly in *Caesar's Column* (1890) carried the injustices of class exploitation to a point, a hypothetical century later, when wealth and political

power are joined in the same ruling elite. In *The Iron Heel* (1907), Jack London began the reign of plutocrats soon after the last free election, in 1912, and continued it for three centuries.

Donnelly's solution, following a crisis that arouses the innocent but beastly urban mob, is for the good people to escape to Africa, where they set up their utopia built on brotherly love and protected by a high wall that keeps the outside world out. London's solution arises within man himself, in his reaction against degradation. And it emerges out of the most depressed and ignored class of menial laborers, the "people of the abyss," who join forces with the kept class of skilled workers and with a few natural geniuses motivated by "sheer love of man." Both Donnelly and London were Marxist in their critiques and utopian in their solutions. But London precociously presented a dilemma that has persisted: the relation between unsophisticated, ordinary man and the cosmic superman whom he sees as necessary to salvation from political repression.

London's striking work, like Zola's, avoids a sentimental belief in the simple goodness of mankind and probes more deeply into the human psyche. London clarified the problem of power with a prescience that portended Orwell. In *The Iron Heel* he envisioned new techniques for controlling the minds of the "masses," including a bomb plot faked by the government. He asserted: "Power is not God, not Mammon, but Power." And he had one of his plutocratic "oligarchs" say, "We will grind you revolutionists down under our heel, and we shall walk upon your faces" ([1907] 1958, p. 83). Some forty years later Orwell wrote, in 1984, "If you want a picture of the future, imagine a boot stamping on a human face—forever" (1949, p. 268).

In *Martin Eden* (1908), London came closest to examining the mind and motivation of his idealized leaders, with their "sheer love of man." In this book the ordinary citizen becomes less an object of sympathy than of pity, and the Nietzschean element in the leader becomes more explicit. London has Martin Eden, torn asunder by his love of both the downtrodden and the distinguished, reflect: "Perhaps Nietzsche had been right. Perhaps there was no truth in anything, no truth in truth—no such thing as truth." Eden says, "I am a sick man. . . . It is my soul, my brain. I seem to have lost all values. I care for nothing. . . . It is too late now." And he drowns himself at sea.

By comparison with his contemporaries London, however lost he was, was not lost in a fog. In *The Octopus* (1901), by Frank Norris, the destructive aspects of capitalism come into false focus. It is

all a battle of the interests against the decent, hard-working, bravely risk-taking farmers. London was caught between Scylla and Charybdis and knew it. For his contemporaries, like Norris and Donnelly, power remained a murky mystery, and they walled it in it exquisitely.

For Paul Leicester Ford, power was neither a murky sea nor a rocky shore. It was something that one simply seized and used—like an adolescent grasping a gyrocompass but not trigonometry. The hero of his *Honorable Peter Stirling* (1894) wins both the governorship and a fair young lady, almost simultaneously. Stirling, in his long, stolid, and solid evolution from a boor to the beloved and just champion of the poor, shuns demagoguery and observes neither more nor less than a firm respect for the just interests of the rich. Like London's hero in *The Iron Heel*, Stirling is animated by a pure love of mankind, but he works in a simple, sweet, manageable world.

Writing in a fictional milieu that took class conflict as a given, Ford and Norris (and Anthony Trollope in *Phineas Finn*) remained not seriously dismayed by the problem of power. Like a mad mariner, London pointed in anguish toward the twentieth century, which people had entered but were not yet in, and foresaw the techniques and consequences of complete social control.

The racial conflict

Another major tributary of political fiction deals with the kind of status that is not a consequence of property differences but of race. Writers have appraised this political problem in both the colonial and the intranational context. The issue is indeed raised by Shakespeare in *Othello* (c. 1604), and Swift's *Modest Proposal* (1729) protests the inhuman status to which Englishmen relegated their Irish subjects. But it was not until the twentieth century, when E. M. Forster wrote his *Passage to India* (1924), that a broad and deep statement was made of the consequences of the conjunction of one race that calls itself master and another that acknowledges and protests its own subordination. Forster analyzed hierarchy by observing the effects of racial status as it was superimposed by conquest on a culture where status was already indigenously and meticulously imposed by caste and religion. He probed intimately into the relations between individuals who try to see others and themselves as individuals but who cannot escape the differences of status and are not much helped by the abstract egalitarianism of Christianity and Islam.

The basic conflict is not oversimplified but is reduced by Forster to that of loyalty and affection

between individuals as they are inhibited and restricted by the bonds of religious, social, and national status. In the novel, Forster implicitly argues for the greater value of individual ties of affection, basing this on his supreme valuation of individuality as more important than religion, caste, and nation. Forster also wrote: "If I had to choose between betraying my country and betraying my friend, I hope I should have the guts to betray my country."

Poignant statements of the problem in an African context have been made by Alan Paton, in *Cry, the Beloved Country* (1948) and *Too Late for Phalarope* (1953). In both, individuals try to reach each other across the chasm of racial distinction. In the second, the sexual aspect, clearly present but not dominant in *A Passage to India*, becomes a central theme—the fascination of forbidden fruit and the spontaneity of physical interpersonal love, which closes its eyes to skin color.

The etiology of the endemic disease of racial tension, as it affects both individuals and politics, is classically stated and explored in these three novels. The dynamics as they operate within a nation have been inevitably stated in America, with its centuries-old dilemma of relations between whites and Negroes. These writings have had little overt political content, from Stowe's *Uncle Tom's Cabin* to Lillian Smith's *Strange Fruit* (1944) and Robert Penn Warren's *Band of Angels* (1955) and his epic poem *Brother to Dragons* (1953). The more recent work of Negro authors, written with an intensity that cannot ever be attained by white writers, has also been largely apolitical.

What is remarkable is the enormous political influence such fiction has had. It is not true that any one book (or any other force) has by itself impelled a social or political movement, but these writings have at times helped raise the strong winds of opinion to hurricane force. Literary discussion from the 1850s to the 1950s of race relations, in intranational, colonial, and latterly in foreign-aid contexts—e.g., William J. Lederer and Eugene Burdick's *The Ugly American* (1958)—indicates the persistence of this politically explosive issue. [See HUMAN RIGHTS.]

Political equality and individual dignity

A common theme of social novels with status preoccupation—whether it be economic or racial in origin—is the equality and dignity of the individual human being. The criticism of discrimination on the basis of class or race rests implicitly or explicitly on the belief in equal dignity or equal

worth, regardless of bodily or economic circumstances over which the individual has no control.

Another category of writings reverses this theme and looks at what can happen when the principle of equality as the only end is assumed and any means appropriate to its achievement is morally justified. From Dostoevski in *The Possessed* (1871) to Henry James in *The Princess Casamassima* (1886) and Joseph Conrad in *The Secret Agent* (1907) the antianarchic critique of amoral equality has stressed the need for decency, honor, and integrity on the grounds that monistic egalitarianism produces only the destruction of orderly society and ultimately the nihilistic negation of the individual himself.

The egalitarian context in which these three novels were written is socioeconomic. They say in effect: What you people like More, Trollope, Chekhov, Hugo, and Dickens are talking about is all very well, but if you altogether succeed, what then? Are you quite sure your poor, sat-upon, proletarian egg will not be hatched a hawk?

The theme of racial equality has undergone a similar attack more recently, in a pair of novels: Robert Ruark's *Something of Value* (1955) and Nicholas Monsarrat's *The Tribe That Lost Its Head* (1956). With a querulous, lascivious dwelling on the terrors of extreme brutality, these novels present at most, and only by implication, a ritualistic solution to the dilemma of inequality (return to the decent, humane virtues of the aristocratic race), but they do succeed in presenting the problem in a crude fashion. The recoil by such as Dostoevski, Conrad, and Ruark at some of the consequences of equality poses the question of the exercise of power without stint in a society dedicated solely to the proposition that all men are created equal. These writings are reactionary without being atavistic: indeed they radically criticize the atavism resulting from unconstrained equality.

Opposition to anarchy and tyranny

The dialogue between the proponents and opponents of socioeconomic and racial equality skirts but never directly enters the area of political power exercised for its own sake. It deals with the adjective rather than the noun, with wealthy or racist power in politics rather than power itself.

The moral problem of political power itself was posed as early as the fifth century B.C., in Sophocles' *Antigone*. In the more abstract form of a man's relation to his God the problem was posed in the Biblical story of Job (probably fifth or fourth century B.C.), who achieved no peace until he

surrendered to the divine will and recognized the gracious omnipotence of his almighty Lord. In Shakespeare's *Macbeth* (c. 1606) the conscienceless pursuit of power at last pricks the conscience of its pursuer, but his destruction is at the hands of society. In Herman Melville's *Billy Budd* (1891) authority (that is, sanctioned power) and simple human virtue come into conflict, virtue bowing to power. A variation of the Billy Budd theme occurs in Herman Wouk's *The Caine Mutiny* (1951), the difference being that the story ends well: both authority and humane justice prevail and all's well. In C. Virgil Gheorghiu's *Twenty-fifth Hour* (1950), law, authority, order, chaos, and the machine combine to destroy the individual.

These direct statements of the power problem do not, however, bore into its origins and its portents. Starting in the 1930s, a brilliant succession of novels has probed man's soul, with a skill showing the enormous impact of Freudian depth psychology. The proliferation of these remarkable works and their failure to fit into a chronological development makes it necessary to consider them by type rather than time.

In his *Brave New World* (1932), Aldous Huxley portrays a 26th-century utopia (or an antiutopia, if More's Utopia is deemed a good society) where people have become truly contented as a result of the elimination of disunity and disorder through the use of both eugenics and childhood conditioning. Only in a genetic sport, a man who developed in a neglected portion of the earth to which conditioning has not yet made its way, is the serene pattern disturbed. Both frightening and at times hilarious, the novel lacks the somber quality of later penetration into individual and social psychology. Karel Čapek's *War With the Newts* (1936) continues the theme of a conformist utopia, portraying a primordial, slimy horror that Huxley's happy English background fails to elicit in print.

André Malraux's *Man's Fate* (1933) is a poignant portent of intensified horror, as the jungles of psyche and society are more deeply explored. Instead of setting his story in European "mass" society, Malraux placed his picture of the human condition in an Asian context, the naked power contest in 1927 between Chiang Kai-shek and the Chinese communists, a conflict Malraux himself had witnessed. In *Man's Hope* (1938) he continued the argument, now set in the Spanish Civil War—which he again saw firsthand. *Man's Fate* is an almost despairing account of cynicism, both individual and governmental, of egocentricity, and of a tiny, nearly extinct spark of human compassion

that keeps man's fate from being quite hopeless. *Man's Hope*, in a kaleidoscopic, almost incomprehensible picture of air and land battles, seems to kindle the spark of compassion into a flickering flame that slightly warms both of the warring camps in Spanish society, and in human society in general.

Building at least systematically, if not actually, on the somewhat impersonal social accounts just discussed, the Italian writer Ignazio Silone increasingly personalized the power problem. In *Fontamara* (1934) and *Bread and Wine* (1937) the ordinary people are more fully drawn than are Malraux's. And a new feature—the top political leader, the chief of state—emerges somewhat dimly in the background. This character is absent or distant in the work of Huxley, Čapek, and Malraux. The dilemmas of ideology, utopia, simple affection among human beings (and its savage antithesis: sexual rape) are conjoined with a simple superstition among the peasantry that takes the form of fear of the leader combined with a feeling of his inevitability, his power, and his grace. Both the peasantry and the politically declassed members of the ruling elite are juxtaposed to the leader in passionate ambivalence.

Three later novels move the ruling class farther into the foreground and the ordinary citizenry into the background. Two of these are psychologically distinguished and logically brilliant; the other, with one or two exceptions, is unsurpassed in its psychological penetration. In *Animal Farm* (1946) and 1984, George Orwell carries to their logical conclusions certain tendencies already well developed in modern industrial society. *Animal Farm*, the allegorical polity in which all animals are equal but the ruling elite of pigs is more equal than the other creatures, argues that ideology and social justice are trivial matters when they confront the lust for power. In 1984 simple, spontaneous, uncontrived, uninduced love, of course, loses the battle, and Winston Smith, mentally *in extremis*, betrays his beloved Julia and comes to love Big Brother himself.

The third of these three novels, Arthur Koestler's *Darkness at Noon* (1941), synthesizes the author's personal experiences in the Spanish Civil War, during which in 1937 he was in solitary confinement in a Seville prison for three months (two months incommunicado), and his earlier experiences as a communist and a newspaperman traveling as an honored guest in the Soviet Union.

The protagonist of the novel, Rubashov, is a composite of several Soviet leaders who were tried

and executed during the Soviet purge trials of the late 1930s. He is a composite of ideologism, courage, intellectuality, opportunism, and atrophied compassion. His life deftly poses several fundamental questions of political power: What means justify what ends? What is truth? When may proximate falsehood be used in the interests of ultimate truth? What is the individual's usefulness, his dignity, and his value?

The book contains several tragedies: the destruction of love between man and woman, to serve party purposes; the exposure of a man's soul in ludicrous public display, to serve party purposes, and the destruction of a party faithful when his usefulness has passed. These tragedies are conjoined with two politically deeper ones—the growing compassion shown Rubashov by a never-seen fellow prisoner, an adherent of the old regime with whom he has nothing in common save uncultured humanity and the inability of Rubashov to live outside the quite corrupt church of the Communist party, in which he has spent his life and the only thing to which he is dedicated aside from self. Neither the compassion of others nor fidelity to party saves him from destruction. In the end Rubashov can choose neither to stand with his fellow men nor to stand alone.

The early antiutopias of the 1930s and 1940s were relatively impersonal and dealt mainly with ordinary citizens. The more personal, and more real, accounts of Silone, Malraux, and Koestler move partially or completely from treatment of the ordinary to the extraordinary citizen, to the declassed member of the ruling elite. Two additional novels dealing with the same problems of unconstrained political power are fictionalized biographies of actual chiefs of state. Robert Penn Warren's *All the King's Men* (1946) follows closely the life of the American Huey P. Long, Louisiana's hypertrophied ruler without scruple in the 1930s. Peter Abrahams' *A Wreath for Udomo* (1956) fictionalizes the life of a prominent African chief of state whom Abrahams knew when both were in London as students and radical African nationalists.

Like Koestler's writing, *All the King's Men* juxtaposes a set of tragedies, the personal and political. There is the use and betrayal of people, the abuse of truth and the use of falsehood, the passionate sense of abstract justice combined with the enthusiasm for inducing a lawless personal dependency—revenge and grace without justice. The tragedy lies in the inability of the leader, Willie Stark, to extricate himself from the personal nest he has woven for himself and then befouled.

Though lacking the somber quality of *Darkness at Noon*, *All the King's Men* ends in deeper tragedy, because instead of being entrapped by circumstance—a party and its ideology—Willie Stark, like Macbeth, is unable to escape himself and death at the hands of a close associate.

A Wreath for Udomo similarly conjoins the personal and the political. Udomo is beloved by and loves a mature Englishwoman he meets in London. He betrays her by having an affair with a mutual friend. When he later gets established as leader of his newly liberated African nation, he sacrifices the life of an old friend and devoted follower, as the price for getting technical aid from the hated, white-ruled nation of South Africa. He is at last killed by tribal atavism, the fear-driven reaction to the modern ways Udomo is introducing.

Most of these antianarchic novels (from Dostoevski to Conrad) and antityrannic novels, often mislabeled antiutopias (from Huxley to Abrahams), were written in western Europe. Out of eastern Europe, in the post-Stalin era, has come a series of novels that offer the promise, and no more as yet, of the re-emergence of intensely political writing in the land that produced Dostoevski and Gogol. The new books remain timid, uncrafted products, still too close to tyranny itself to be able to appraise it freely. Among these are Vladimir Dudintsev's *Not by Bread Alone*, more concerned with public administration than with public policy; Abram Tertz's *The Trial Begins* (1960), which deals directly if crudely with Stalinist tyranny; and Alexander Solzhenitsyn's *One Day in the Life of Ivan Denisovich* (1963), which considers the theme of selfishness and the platitude of the endurance of the human spirit, but otherwise is undistinguished. It nevertheless is a milestone in the public recognition it has accorded the author in the Soviet Union, where he was nominated in 1963 for the Lenin Prize.

Nietzschean and anti-Nietzschean themes

There remains still another category of political novels, incongruous among those that oppose either anarchy or tyranny. These are the writings that implicitly or explicitly espouse and justify—or reject and condemn—a Nietzschean, individualist anarchism divorced from any social or socialist commitment. In a sense, these are antipolitical works.

A prototype of this genre is Stendhal's *The Red and the Black* (1830). Its protagonist Julien moves through life and through people's lives with a moral dedication to self that rises above any less exalted purpose. He pushes into boudoirs and the bureaus

of business and government with a purity of heart that beguiles. At the end he faces trial with a moral courage and a refusal to compromise his principle that makes it easy to overlook the principle to which he was dedicated. If the pure in heart ever are to see their God, Julien saw his in himself and was by himself blest.

The Red and the Black is indeed a pure novel, unbesmirched by the dilemma between individual distinction and social service. If the solution for Martin Eden was the escape of private suicide, Julien went to his public execution with the courage of Socrates and Christ, the sole difference being in the diverse principles for which Julien and Socrates and Christ died.

Two more-recent novels echo the *Red and Black* theme, in one case with several inklings of awareness of the dilemma and in the other with no more than an inkling. Hermann Hesse's *Steppenwolf* (1927) is the story of an individualist who moves from the writing desk to the dance hall, discovers affection for others, but does not swerve dangerously from his self-dedication. For a while, nevertheless, he enjoys warming and being warmed by others.

Not so Dr. Zhivago, in Boris Pasternak's novel by that name (1957). With a dedication to self that rivals Julien's, Zhivago moves endlessly across the well-limned Russian landscape during and after the great revolution, sloughing off those whom he has used and who have become attached to him. He does it all with a remarkable sense of high purpose, blaming only the chaos and the Soviet system for his faults, that is, his inability to succeed altogether in his self-service. The critical enthusiasm with which the book was received after its official Soviet condemnation and the awarding of the Nobel Prize to its author reflected a pharisaical condemnation of Soviet communism and no understanding of the refusal of Pasternak to face the dilemma confronted by London, Koestler, and Orwell. In *Dr. Zhivago*, Nietzsche is not problematical but axiomatic.

Two individualistic American novels throw this issue into relief: James Gould Cozzens' *The Last Adam* (1933) and Ernest Hemingway's *For Whom the Bell Tolls* (1940). Both emphasize individual values and candidly make their protagonists into heroes. Both clearly indicate a commitment of these heroes to their communities. There is a consequent warmth in Cozzens' and Hemingway's characters that contrasts with the vibrating chill of Julien and Zhivago.

A brilliantly madcap Italian drama on egocentricity, Luigi Pirandello's *Six Characters in Search*

of an Author (1922), mixes tragedy and comedy as his protagonists step in and out of character as concupiscent egoists exploiting one another and protesting their altruism. Obviously nonpolitical, this pungent play deeply influenced Gamal Abdel Nasser, who viewed the same prurient egoism on the other side of the Mediterranean as a prime cause of Egyptian political impotence before and after the 1952 revolution.

Two French novelists have written on the theme, in works that replace Pirandello's mordant laughter with a moan from the wounds of egoism that rises to a cry of mortal despair. The existentialist Jean-Paul Sartre in *The Age of Reason* (1945) has his characters search for private freedom, after liberty has been publicly betrayed in the Spanish Civil War. They seek it in the paradox of uncommitted love that exploits others for their companionship and passion but ends in solitude. At the last the central character muses that he is "alone but no freer than before. . . . this life had been given him for nothing, he was nothing and yet he would not change: he was as he was made" ([1945] see 1959, p. 342). In Sartre's *Troubled Sleep* (1949), set in France during the Nazi occupation in 1940, the search for freedom is similarly fruitless. To personal egoism is conjoined national egoism: man cares neither for man nor woman nor *Vaterland* nor *patrie*—and vice versa. All one can do, Sartre seems to say, is endure, clutching the thin coin of existentialism whose other side is nihilism.

The cry of Albert Camus is even more piercing. In *The Plague* (1947) he seems to argue with Sartre's morbid description of man's isolation. In an allegory of France during the Nazi occupation, he finds individual men who dedicate themselves warmly to a solidary, compassionate succoring of the plague-stricken community. Fear of fatal infection and mistrust of one's neighbors are overcome by the "craving for human contacts" and the identification with the dying. Society must endure, and with individual compassion for individuals it can endure. "The Stranger" in Camus's 1942 novel by that name is an emotionally empty man who kills without feeling, without even hatred, an alien in a community whose members remain individually and collectively united against their asocial fellow citizen. But in *The Fall* (1956), Camus appears to have surrendered to despair. There can be no conjunction of freedom and society. Solitude is unbearable, and man cannot bear freedom, a court sentence imposed on oneself by oneself. Man must be a slave, in a society where all are slaves to their own inescapable egoism. Lacking love, men are dragged through life by their almost

impotent hypersexuality. Their common guilt can hold them together, but it only delays the solitude of death.

And in Ingmar Bergman's screenplays the theme is repeated in Scandinavian settings, with the sharp skill of London, Sartre, and Camus but without their resignation or despair. In *Wild Strawberries* (1957), a distinguished septuagenarian scientist, about to be honored for his dedicated pursuit of reality, in his dreams sees himself as indifferent, unloving and unloved, living in deadly solitude. "I'm dead, although I live." In the triad of screenplays *Through a Glass Darkly* (1961), *Winter Light* (1963), and *The Silence* (1963), the theme is reinforced: psychoanalytic understanding, piety, and sexual passion without love do become deathly futile and impotent. But, Bergman insists, men are capable of compassion.

The problem of free choice

Political fiction, like political science, has always been a product of the developing stage of culture in which it was written. Both fiction and science have drawn from the same intellectual sources and appraised the dilemmas of the time. When the very idea of limited government was taking shape, Sophocles in *Antigone* raised the radical issue of civil disobedience. In the twentieth century, when tyranny underwent another revival—perhaps unequaled since the savage sixteenth century of the Reformation and Counter Reformation—the theme of tyranny again became central.

But political fiction now reflects the infusion of new knowledge, notably from psychology and physiology. It has consequently produced an inquiry into the causes and consequences of tyranny that is remarkable in depth and suggestiveness. In so doing, political fiction has articulated analyses of problems that in contemporary writing in political science have had largely disjointed treatment: the relationship between the individual, his fellow men, his fellow citizens, and government; the concept of justice in which government is more than an arbiter between citizens; the problem of moral choice and free choice; and above all, the criteria for choice.

Indeed, to a great extent the new political theory of the twentieth century has been written in fictional form. Some writings already discussed and some not yet discussed show this sharply.

In 1984 Orwell develops his story and his theory by employing an almost classic Freudian thesis. Government, to control individual political loyalty, must sever ties of loyalty between individuals. The basic tie, says Orwell, following Freud, is the

erotic one—physical love with its attendant personal affection. To break this tie, government must destroy physical desire. To do this, government must, in turn, reactivate the primordial individual desire for sheer survival and replace love between real people with the childish dependent love for the never-seen omnipotence that graciously or tyrannically permits survival and provides the means for survival. Heterosexual love is replaced with asexual childish dependent love, and political autonomy is replaced with political infancy. Justice is controlled by what through "doublethink" is called the Ministry of Love, where men are reduced to impotence.

Koestler in *Darkness at Noon* offers a more complicated set of hypotheses. Love and loyalty between individuals are indeed deadened by tyranny. But the problem of justice gets a less stark, more subtle and realistic, consideration than Orwell's brutal statement that power is a boot stamping on a human face forever. Justice now relates to means and ends. As object and subject the individual is considered by Koestler to be a commodity to be valued quite apart from his usefulness to the polity. But can man choose? With a vague, attenuated humanitarianism that becomes entangled with the justification of any efficient means to humane ends, Rubashov chooses only to condemn himself. A socialized, collectivized Nietzschean, he can exercise his will only by conforming to the will of the political party, which has become identical with the will of the leader. Koestler seems to say that men can be aware but not choose.

The problem of free moral choice (a tautology, at least in politics) gets precocious emphasis in Joseph Conrad's *Under Western Eyes* (1911). With or without the benefit of psychoanalytic theory, Conrad poignantly refines the problem. He indicates that the consequence of choice, when it destroys other people, is to destroy the chooser.

The criteria for choice are considered in two of the first works which deeply explore political behavior. In the theoretical dialogue between sexual and nonsexual love (eros and agape), both these novels employ depth psychology and argue against a simplistic Freudian erotism.

Franz Kafka in *The Castle* (1926) has his protagonist, K., use sex to get ahead, to try to get the attention of the leader, the unseen chief in the castle. The wretch K. fails because, like Julien and Zhivago, he is concentrated all in self and at last can only throw himself on the infinite mercy that accompanies infinite power.

William Golding in *Free Fall* (1959) evidently rejects his earlier thesis in *Lord of the Flies* that

beneath man's enculturation crouches only a primordial beast. He now argues that man cannot live alone, that he must live with and for other individuals, and that the dilemma of living for oneself and for others will persist and is the basis for guilt, which also will persist. Man is not altogether formed by either his genes or his environs: he can choose, with inevitable guilt, but without guilt he could never make choices that are right—that is, moral. He can never help establish a free society or free himself without considering the consequences of his choices both for himself and for others.

In so stating the criteria for choice, Golding avoids the surrender to divine will implicit in the Biblical Job and the modern *Castle*, to the will of the party and leader explicit in *Darkness at Noon* and 1984, and to individually uncontrollable forces as in *Martin Eden*. *Free Fall* thus implies there is choice, that forces within and without the individual are not altogether uncontrollable, and that anxiety and guilt will inevitably accompany the exercise of choice. To this extent Golding indicates a way out of the dilemma so poignantly posed by London.

All these factors have been integrated in unequaled, necessarily epigrammatic form in a political novella of classic proportions, *Mario and the Magician* (1929) by Thomas Mann. In *Mario* are fully presented the leader, the citizenry that is led, and the citizen who kills the tyrant. The roots of tyranny are exposed in the leader's envy, contempt, and hatred for the public and in the public's moral obtuseness that considers politics a game at which they are irresponsible spectators. And using the need for people to huddle together, the leader isolates potential dissenters. In a brilliantly contrived denouement, Mann has the leader exploit and pervert sexual love and be undone by a young man whose revulsion at the leader seems to stem from the depths of the untutored, natural man. Mann in this rather short story does not explicate other political fiction; he epitomizes it.

If the themes of private and public egoism, tyranny, and free choice had not recurred in Russian, English, Italian, French, German, and Swedish writing, in contexts scattered over centuries and over the globe, one might argue that the condition was not universal but parochial. In Malraux and Golding, the dying despair of Dostoevski, Orwell, Pirandello, Sartre, Camus, Koestler, and Kafka is quickened by hope. Man need not just exist and then cease: he can elicit his own compassion and can redeem himself and his fellow men. Deepened psychological understanding need not just witness

or contribute to the destruction of men and society; it can help build both. Man is helpless neither against the tyranny of his own egoism nor against the tyranny of egoism in the general public and its leaders.

Political fiction and political science

One conclusion from a look at political fiction is that the lines between fiction, theory, and fact are very indistinct. *Darkness at Noon*, a fiction piece about the great Soviet purges of the late 1930s, portended not only the factual account of them in Beck and Godin's *Russian Purge and the Extraction of Confession* (1951) but also the profound study of brainwashing in Lifton's *Thought Reform and the Psychology of Totalism* (1961). In a sense fiction here was a decade ahead of published fact and two decades ahead of systematic theory and observation. Koestler in turn was building on fact. Bukharin, one of the most distinguished victims of the 1938 purge, said at his trial: "When you ask yourself: 'If you must die, what are you dying for?'—an absolute black vacuity suddenly rises before you with startling vividness. There was nothing to die for, if one wanted to die unrepentant" (quoted in Daniels 1960, p. 389).

In raising basic issues of power in its political manifestations and of the ability and responsibility to make choices, political fiction has been working in the same garden as have political theory and political research. The far from accidental consequence is that political fiction has posed problems and stated solutions that are rarely behind, and often ahead of, the statement and resolution of these problems by more prosaic investigators. There is a relationship between Job's argument with his God, Antigone's with her king, and Winston Smith's with his Big Brother. There is a tie between Freudian theory, Marxian socioeconomic theory, and the writings of Koestler, Golding, and Bergman. Each supports and facilitates the understanding of the other. One very notable distinction is that the fiction writer puts the reader on guard, since the reader of fiction realizes that what is being written is not necessarily ultimate truth or exact fact. The nonfiction theorist or researcher in politics seldom so protects the reader. In this sense writers of political fiction are exercising a responsible moral choice as to the canons of scientific method that is too infrequently faced by writers of political science.

LLEWELLYN, KARL N.

Karl Nickerson Llewellyn (1893–1962) was a leading exponent of "realism" in the field of jurisprudence. Applying the realistic method to commercial law, he produced the Uniform Commercial Code, now effective law in the United States. He also wrote on legal education, emphasizing craft skills and law as a liberal art, on the professional responsibility and organization of the bar; and on the sociology of law. He analyzed law-government as an institution and demonstrated that dispute settlement is the most reliable indicator of the law and values of a group. In addition, he wrote poetry, painted, and composed songs.

At Yale, where he studied both as an undergraduate and as a law student, his exposure to the ideas of William Graham Sumner, through the lectures of A. G. Keller, aroused Llewellyn's interest in patterns of behavior as fundamentals in societal structure. He was influenced by the fact-to-result analysis of cases used by Arthur L. Corbin and by the narrow-issue thinking of Wesley Hohfeld and Walter W. Cook. After teaching commercial law at Yale for two years, he went into practice in New York City, studying banking and business patterns as well as the crafts of counseling and advocacy. When he returned to Yale, his writings reflected his preoccupation with the relation of commercial practice and economics to law; his work also revealed his expanding interest in legal sociology.

He admired Holmes, Pound, Cardozo, Max Weber, and Eugen Ehrlich. Starting in the 1920s, he drafted legislation for the Commissioners on Uniform State Laws; at the same time, he examined the process of rule making in its theoretical and practical aspects. Llewellyn's move to Columbia in 1924 coincided with the ferment there concerning the merits of fact research and of the integration of law with the other social sciences. His major study of commercial doctrine, factual patterns, and the ways in which cases reflect social conditions, business practices, and styles of judicial decision led to his *Cases and Materials on the Law of Sales* (1930a), a classic introduction to the study of law; *The Bramble Bush* (1930b); and a set of lectures delivered in Germany and entitled "Einführung in das amerikanische Präjudizienrechtswesen."

His publication of "A Realistic Jurisprudence—The Next Step" (1930c) precipitated a controversy about the nature of realism. Llewellyn saw realism as a method of attacking legal problems by first looking at what was in fact being done by courts and other officials. In this connection, he insisted on the importance of narrow, factual categories and the temporary divorce of "is" from "ought." He read cases for their narrow holdings (the facts, precise legal issue, and result), testing whether the courts were doing what doctrine seemingly required. The objectives of this analysis were, first, an accurate statement of the operative law; second, a testing of the relation between that law and the life situation it encompasses; third, an evaluation of the policy thus reflected; and finally, a decision as to what the law ought to be, and its statement in a well-drafted legislative or judicial rule. He saw legal rules as vital to the guidance and control of behavior and urged that these rules explicitly state their reason and that they be accompanied by explanation of the policy on which they rest. He believed that the Janus-faced nature of precedent forces courts to make policy choices and that courts cannot operate effectively in our society without such leeway of choice. He urged recognition of this fact as a first step to better decisions. Few scholars have been more interested and more active in the process of rule making and in relating law to values, and none has been more falsely accused of being concerned only with the "is."

Already active in the Legal Aid Society and the American Civil Liberties Union, in the 1930s he also helped plan strategy for the National Association for the Advancement of Colored People. His commercial-law articles became increasingly con-

cerned with the relation of judicial method, institutional structure, and practice to the development of doctrine.

A study he made with E. A. Hoebel of the law-government of the Cheyenne Indians resulted in *The Cheyenne Way* (1941), which broke ground in anthropological method. In *The Cheyenne Way*, Llewellyn departed from the traditional procedure of inferring the character of the law from the statements of informants; his methodological innovation was to try to determine what the effective law of the group was—what happened in actual conflict situations.

His writings in jurisprudence reflected his view of law-government as an institution with its own functions, values, crafts, and traditions. He used "law-government" to designate the total legal component of society. It includes the mechanics of dispute settlement; the allocation of the power to decide particular types of issues; and the formulation of substantive rules, whether by legislation, executive action, or judicial decision. The concept of law-government rejects the view that the law is simply a body of rules; instead, the law is considered to be a set of institutions.

In the 1940s Llewellyn's theories of rule making and his perception of the appellate process bore fruit in the style of organization and drafting of the Uniform Commercial Code. His insistence on preliminary analysis in terms of narrow issues and narrow factual categories proved its value in the resulting clarification of the policy considerations involved in this legislation. He also studied the law-government of pueblo groups and drafted legal codes for the Santa Ana and Santo Domingo pueblos. In 1944, as chairman of the Curriculum Committee of the Association of American Law Schools, he made a report, which has become a classic, analyzing legal crafts and skills as they relate to legal education (see Association of American Law Schools 1944). His Storrs lectures at Yale Law School foreshadowed Llewellyn's *Common Law Tradition: Deciding Appeals* (1960), a definitive statement of the appellate process. In 1948/1949, while a visiting professor at Harvard, he prepared a jurisprudence syllabus incorporating his view of law-government.

In 1951 he moved to the University of Chicago, attracted by the ideas of Edward H. Levi, dean of the law school. At Chicago he concentrated on the development of his jurisprudence syllabus, the refinement of materials on legal argument that he had been collecting since 1934, and the completion of his study of the process of appellate judging. His

writings in legal education deal more directly with questions of craft, scope, and responsibility, and he explored further the relationship of law to the humanities, as well as to the behavioral sciences.

LOBBYING

If we had data on every government in every culture, we would probably find that lobbying in some form is an inevitable concomitant of government. The term originated in American governmental experience about 1830. Certain representatives of interest groups loitered in the lobbies off the assembly halls of the American Congress and

state legislatures, hoping to get a chance to speak to legislators and thereby attempt to influence their decisions. As the term became part of the vernacular, it was broadened to include anyone who attempted to influence the decision of a governmental official. The term is currently used quite loosely, and often inappropriately, for all kinds of influence endeavors. Since it is popularly believed that lobbyists use improper methods in their attempts to influence officials, the term "lobbying" carries an unpleasant connotation to many minds.

Despite the imprecision of the current use of the term, some boundaries can be defined. (1) Lobbying occurs only in governmental decision making. Decisions made by private individuals, organizations, or corporations may be influenced by special interests, but the influence should not be called lobbying. (2) All lobbying is motivated by a desire to influence. Many actions and events may affect the outcome of governmental decisions, but if they are not accompanied by an intent to influence, there is no lobbying. (3) Lobbying implies the presence of an intermediary or representative as a communication link between citizens and governmental decision makers. A citizen who, of his own volition and by his own means, sends a message to a governmental decision maker is not considered a lobbyist even though he is attempting to influence governmental decisions. (4) All lobbying involves communication, for that is the only way that influence can be transmitted. Broadly defined, then, *lobbying is the stimulation and transmission of a communication, by someone other than a citizen acting on his own behalf, directed to a governmental decision maker with the hope of influencing his decision.*

Although most lobbyists do represent special-interest groups, or pressure groups, lobbying is not identical with interest-group behavior. For one thing, individuals as well as groups utilize lobbying. Second, interest groups engage in many activities in addition to lobbying; some groups, in fact, do not engage in lobbying at all. Third, individuals or groups with special interests may find direct representation without the intercession of lobbyists. Lobbying, then, is but one process or means of representation that individuals and groups might utilize.

Lobbying should be thought of as a process rather than as an organization. It is most helpful to think of it as a communication process by which lobbyists attempt to get governmental officials to accept the policy desires of lobbying clients. It is the lobbyist's job to create messages

and to choose means of transmission that are most likely to ensure clear and favorable reception of the message by the intended receiver. This means that the lobbyist must anticipate the predispositions of his intended receiver(s) and so act that the message will be favorably received with as little distortion as possible. He must take care that the message is not intercepted or blocked. He must choose a transmission channel that is open (has access), is not likely to be overloaded, and has a low noise level.

The origin of the term "lobbying" and its legal definition in the United States statute, the Federal Regulation of Lobbying Act of 1946, leads many persons to believe that lobbying applies only to legislative decisions. The definition given above suggests, however, that lobbying occurs just as readily with executive-branch officials as with legislators, and even to a certain extent with judicial officials. Empirical data for the United States national government show that executive-branch lobbying is just as prevalent as legislative-branch lobbying (Milbrath 1963, pp. 319-320; Cherington & Gillen 1962).

Patterns of lobbying

Although there have been studies of interest groups in a number of countries, studies of the lobbying process are relatively rare and nearly always confined to the United States. Consequently, little is known about how lobbying is conducted outside of the United States. It does seem clear, however, that only in the United States are large numbers of special political actors designated to play the role of lobbyist on a full-time, professional basis. Most of the persons who perform lobbying functions in other national cultures probably do so as a part-time activity while maintaining a major role as an interest-group official, labor union official, attorney, or corporation executive.

For lack of empirical evidence, one can only speculate on reasons for the greater emphasis on lobbying in the United States as compared with other countries. One possible reason is that representation of interests is more clearly built into the governmental system of other Western countries than into the American governmental system. Interest groups, in these other countries, are given seats on advisory boards or are consulted as a matter of course by ministers or bureau chiefs. In addition, interest groups often succeed in electing one or more of their own men to seats in the legislative body. Of course, these things also occur in American government, but the difference in

emphasis is substantial. American interest groups believe they must take the initiative if they hope to be heard at decision time.

Another possible reason for the difference in lobbying between America and other Western countries is the difference in centralization of decision making in the government. In most Western governments, decision making is highly concentrated in the cabinet executive, whereas in the United States it is divided between the executive and the legislature, and sometimes between the state and national governments. A diffuse decision process, one that has many decision points, more likely requires continuous scrutiny and pressure by special interests in order to get a policy moved past each of these points. In a sense, lobbying must be used in a diffuse decisional system to avoid degeneration of the system into inaction or stalemate.

Differences in the political-party system also seem to affect lobbying. European parties are more closely allied with and based on interest groups (especially in multiparty systems). Generally, they also are more "responsible" (able and required to carry out their program when given power) than American parties. American parties are so heterogeneous that they must compromise group interests rather than clearly speak for them. Furthermore, American parties cannot be counted on for firm policy leadership. Interest groups in the United States have almost abandoned working through parties and instead have hired lobbyists to secure policy representation (Milbrath 1963, p. 200). By way of contrast, European interest groups are more likely than American interest groups to find political parties a useful means of representation and to depend to a lesser extent on lobbying (Beer 1958, p. 138).

During the initial stages of lobbying's development in the United States, some groups sought competitive advantage over other groups by sending a personal envoy (a lobbyist) to the seat of government. Lobbying at this stage was very much a function of the direct personal relationship between lobbyists and official decision makers. Groups with more competent lobbyists were more likely to have their messages accepted by government officials. Groups at a competitive disadvantage because they had no lobbyist were stimulated also to send a lobbyist envoy. Eventually, the seat of the national government, and also the seats of some state governments, became crowded with lobbyists clamoring for an opportunity to deliver direct personal messages to officials. Easy access for direct communication between lobbyist and

official, which had been possible with only a limited number of lobbyists, became very difficult. (Currently there are between eight hundred and one thousand registered lobbyists in Washington, D.C.)

Faced with a situation where the channels of direct communication with officials were constantly overloaded and seldom available, lobbyists turned to indirect communication methods. They sent messages through intermediaries who were thought to have better access, such as constituents or friends of the officials. They stimulated mass letter or telegram campaigns, hoping to impress officials with a ground swell of public sentiment for or against a policy. They launched massive public relations campaigns in the mass media, hoping to change (or maintain) political attitudes. This shift of tactics to indirect communication methods became known as "lobbying at the grass roots."

However, indirect methods also are limited in effectiveness. Grass-roots campaigns conducted by strong competitive groups often result in stalemate or *status quo*. Campaigns stimulated by lobbyists usually are detected as such by officials, and their potential impact is seriously discounted through knowledge of their nonspontaneous nature. Successful public relations campaigns require subtle management and are very expensive. As a result of these kinds of difficulties, the pendulum has begun to swing back from grass-roots lobbying.

Current lobbying methods in Washington, D.C. are a blend of direct and indirect methods of communication. Direct methods, such as personal presentation of viewpoints, are preferred by most lobbyists, but they cannot be relied on to get messages through to officials. Lobbyists turn to indirect methods when direct ones prove uncertain or unusable. In addition, lobbyists pay considerable attention to the problem of keeping their communication channels open. They employ various means of ingratiating themselves with officials to ensure that access will be speedy and direct when it is needed. Entertainment and bribery are not as widely used to ingratiate as is popularly supposed. They are not considered as rewards or favors by most officials, and bribery especially is dangerous to the careers of both officials and lobbyists (Milbrath 1963, chapter 13).

Lobbying occurs at all levels of government in the United States: city, county, and state as well as national. Research on state lobbying is scattered and uneven, while research on city and county lobbying is almost nonexistent. About three-fourths of the fifty states have a lobby-regulation or lobby-

reporting law, but in most cases these laws are rather weakly enforced.

The scattered research evidence that exists on state lobbying suggests that lobbyists at the state level primarily employ direct methods of communication with officials. Competition for the time and attention of officials is less at the state level than at the national level. Consequently, state lobbyists do not find it so necessary to turn to the more expensive and less certain indirect methods that national lobbyists must employ.

Employing primarily direct methods, state lobbyists devote more time and resources to ingratiating themselves with officials and to keeping communication lines open. The reported incidence of entertainment and bribery is higher at the state level than at the national level. Furthermore, entertainment is considered more of a reward in state capitals than in Washington, D.C. Most state legislators do not establish residence at the seat of government, as most members of Congress do. Living in a hotel, the state legislator generally finds the prospect of spending an evening on a lobbyist's expense account much more appealing than does the overworked and overentertained member of Congress.

The study of lobbying

Lobbying is often studied within the context of some larger process. Four examples of such processes can be given. First, lobbying has been studied as a component of the legislative process (Herring 1929; Gross 1953). Second, it has been studied as a component of the process by which the total government arrives at a decision about a given bill or policy (Bailey 1950; Latham 1952; Bauer et al. 1963). Third, lobbying is a significant component of studies of the group process of politics (Bentley 1908; Truman 1951). Fourth, studies of the nature and activity of interest groups naturally incorporate lobbying activity as a part of total group activity (Garceau 1941; Kile 1948; Taft 1954; Eckstein 1960; Potter 1961).

A much smaller proportion of studies give direct and primary attention to lobbying per se; these fall into three categories. First, Congressional investigating committees have developed valuable information on lobbying in Washington, D.C., usually with a view to possible legislative changes in the regulation of lobbying. Two prominent examples are the House of Representatives Select Committee on Lobbying Activities, which was active in 1949 and 1950 and was chaired by Representative Frank Buchanan of Pennsylvania; and the Senate Special Committee to Investigate Poli-

tical Activities, Lobbying, and Campaign Contributions, which was active in 1956 and 1957 and was chaired by Senator John McClellan of Arkansas. Second, some persons regard lobbying as a threat to free government and believe the process should be exposed from time to time to the glare of publicity. These journalistic exposés are usually more specific and polemical than general and scholarly; two book-length efforts are Crawford (1939) and Schriftgiesser (1951). Third, some recent scholarly work has focused directly on the lobbyist as political actor. Based on first-hand interview evidence, these studies describe the roles of lobbyists as mediators between groups and government and give detailed evaluations of methods and techniques used in the lobbying process (Milbrath 1963; Patterson 1963).

This last approach to the study of lobbying, deriving empirical data from the persons who practice lobbying, seems to shed most light on the subject. To date, such evidence is available only on Washington lobbyists and lobbyists in a few state governments such as Michigan (De Vries 1960) and Oklahoma (Patterson 1963). It is important that such evidence also be gathered in different national political systems. The role of lobbying in the policy-making process will be much better understood when comparisons using adequate and valid data are possible across national cultures.

Evaluation

The paucity of empirical data makes it difficult to give an adequate evaluation of the role of lobbying in the political process. It might be helpful, however, to list some of the utilities and disutilities of lobbying as a part of the political process.

One utility of lobbying is the service (primarily information) that lobbyists and lobby organizations provide to official decision makers. These services are often proclaimed as being free since they do not come directly out of the taxpayer's pocket. In another sense, however, the costs of lobbying are passed on to the public in the form of higher prices for goods and services. Since the public pays for the service in either case, the service should be evaluated according to its quality. The present system of lobbying services makes for considerable duplication and is clearly wasteful and time-consuming. Thus, even though officials make considerable use of this lobbying service, it probably could be obtained from alternative sources at a lower cost to the body politic.

On the other hand, there is something to be said for having alternative and duplicative sources

of information and other services. An official who can turn to more than one source for information is less subservient to any one source. Dispensing with lobbying service probably would make Congress even more dependent on the executive, since Congress generally has fewer adequate information sources.

Perhaps the most useful service is the transmission and clash of viewpoints. This serves a creative function in alerting decision makers to all possible policy alternatives and mitigates a good deal of the waste and frustration involved in lobbying. Officials might find other sources for most services lobbyists provide, but they benefit quite clearly from the representational function that the lobbyist spokesmen for specific interests perform. Lobby groups and lobbyists were evolved as a part of government to fulfill this need for specific representation, a need that no other component of the political process is adapted to fill (Milbrath 1963, p. 313).

A major disutility of lobbying, in addition to waste, is its potential for corruption. Lobbyists usually represent persons seeking specific—therefore private—ends. Such private ends may coincide or be compatible with the public welfare, but, in many instances, they are not. An adequate political system reconciles these private ends to the public welfare, but it cannot do this if officials or lobbyists act corruptly. Corruption enters when the system responds to money or property instead of to votes alone; when personal pecuniary rewards are offered to or accepted by officials as they arrive at decisions; and when decisions are made in secret, thus foreclosing opportunity for dissent from the opposition.

Lobbying in Washington, D.C., has a relatively low incidence of corruption, not so much because of legal controls (which are relatively inadequate) but because of built-in systemic controls of the process. These systemic controls are integral to the total policy-making system. All of the actors in this system are interdependent; no man makes a governmental decision by himself. Furthermore, each actor is vulnerable; he can be punished by someone else if he does not perform according to expectations. Systems having interdependent, vulnerable actors naturally develop rules of the game so that actors may relate to one another with the least amount of friction. There is no room in the rules of such a system for corrupt or deceitful relationships between actors; the potential costs to other actors are too great. Actors who refuse to conform to these rules are readily ejected from the system (Milbrath 1963, part iv).

Lobbying is but one factor in the total policy-making process of any government. Seldom can the predominating influence on a policy decision be attributed to lobbying. Other influences—such as the desires of the voters, the cajolings of fellow officials, and the political philosophy of officials—generally outweigh the impact of lobbying. Yet lobbying makes a useful contribution by injecting the policy desires of special interests into the political system. The range of policy alternatives available to decision makers is probably broader, and the perceptions by officials of the potential impact of their decisions is probably clearer, because of lobbying activity. Assuming that this leads to better-informed and higher-quality decisions, the net contribution of lobbying to the political process is probably positive.

LOCAL FINANCE

Local governments and their financial structures have been subjected to heavy strains by the rapid population growth, urbanization, industrialization, and centralization of the past century. A local government is usually constrained by limited territorial jurisdiction, restrictions on the functions it can perform, ceilings on the amount of permitted taxes and debt, and restrictions on sources of revenue. Not only is its freedom limited, but often most of its actions are ordered, and its behavior then supervised, by the central government. It is no surprise that under these conditions local governments have responded sluggishly to the great technological and institutional changes of the past century. Few generalizations can be made about local finance, since each nation has a different constitution and each has many types of local governments; but one statement which holds for most of the world is that local governments have become weak relative to central governments.

The most common argument explaining the relative decline of local government is a financial one. It is asserted that the most tax-productive bases are pre-empted by central governments and that it is not feasible for a local government to raise its taxes, since industry and persons will respond by moving to other locations. This is far too simple. Throughout the world, localities can be found with

almost every type of tax, and the burden of local taxes is highly variable among nations. The tremendous variation in behavior casts doubt on statements of necessary relationship. Localities do have greater financial problems than do central governments, but solutions that enable the localities to be vigorous and relatively autonomous are available. The relative decline of local government has been accompanied by a refusal fully to exploit purely financial solutions to problems, and it indicates that nonfinancial factors are more significant.

Among nations, the United States has one of the most active sets of local governments, but even in the United States the ratio of federal expenditures on civilian activity to state and local expenditures doubled in the first half of the twentieth century. Despite this relative decline of local governments, in absolute terms local governments have grown greatly in importance. In 1902 local expenditures were less than \$900 million, and by 1964 they were over \$45,000 million in current dollars. State expenditures increased even more dramatically, from \$134 million in 1902 to \$24,275 million in 1964. Per capita state and local expenditures increased from under \$13 in 1902 to over \$360 in 1964. These growth figures are dramatic, but they are accompanied, though to a lesser degree, by the world-wide phenomena of an outright transfer of some functions to central governments and of a shift of financial support to central governments, with a consequent absorption of authority by the central governments.

Given the wide range of experiences in degrees of centralization, any simple set of hypotheses would most likely be wrong. Unfortunately, there has been very little research in comparative local finance, so that sophisticated arguments are not available; therefore, we will have to be satisfied with rather general explanations of the relative decline of local government and finance.

Local government, like the horse and the candle, has been the victim of technology. High among the list of significant technological breakthroughs have been the transportation and communication revolutions, which have greatly reduced spatial costs. While these innovations have completely changed industrial structures, have made markets national and international in scope, and have made resources, as well as production centers, highly mobile, local governments have remained fixed in spatial jurisdiction.

The increase in the size of input and product markets has resulted in a great increase in the number of local governments that can affect the efficient operations of the markets. A system of

roads can be crippled by poor design of one part, or inadequate education in one area may mean a poor labor force for another area to which the population moves. Therefore, the supply of inputs or the market possibilities of a firm in a city may be strongly affected by the behavior of many distant local governments which it cannot directly influence. Mass-production, standardized industry expanded throughout the nation, while local governments remained fixed. It is not surprising that pressures were strong to create uniformity of tax treatment and of public services in the various parts of the nation—a reasonable uniformity which has been effected by transfer of functions to central governments and by central subventions to local governments.

The goal of uniform public service throughout the nation is not restricted to those services which are inputs to industry; it extends to products going directly to households. Uniformity in consumption of public services would not necessarily lead to centralization, were it not for a second major factor. Fiscal resources are not uniformly distributed among local jurisdictions. If localities were to apply similar tax structures to their economic bases, very different yields would result. If they sought to vary their tax systems in order to realize somewhat equal per capita yields and similar levels of public services, they would have highly variable tax systems. This would have the undesirable consequences of complexity in taxation and nonuniform treatment. The latter might encourage mobile resources to move elsewhere to find another structure that might not tax them as severely. Achievement of uniformity in service without too much variation in tax structure requires the transfer of financing to a central government.

The simplest and most adaptable response of government to the changing economy is the design of a central administrative agency which can establish operational rules independent of past conventions and responsive to the new set of needs. This response has been the most common. The transfer of functions to a central government means a centralization of authority, control, and finance; but administration may be as widely dispersed as the pattern of local governments, or it may take an entirely new organizational form. From the point of view of attaining the most effective government response to the need for public services, this total centralization may be best; but the less radical solution of attempting to work through existing local governments is often adopted. Despite the relatively greater growth of the central administration, local administration is still important and

probably will remain so, especially in the United States, where the vitality of local government follows from the constitutionally imposed federal structure and from the structure of political parties, which have their strong base in state and local governments.

Types of arrangements

The nations of the world have invented many financial arrangements by which to support local governments; these arrangements can be ordered into a few categories.

Local taxes on differentiated bases. In the United States the major illustration of a separate tax base is the property tax. The federal government makes no use of the property tax, and state governments have been reducing their use of the tax. Some local governments, especially single-purpose districts like school districts and irrigation districts, are restricted to the property tax. Although the property tax is still the principal support of local government, it has declined in importance; its base has been progressively narrowed as more types of property have been removed from the base and other sources of support have been introduced.

Local reliance on the property tax is not uniform. The average property tax rate for the United States was estimated to be 1.4 per cent of market value of locally assessed property in 1962, but this varied from 2.7 per cent in Massachusetts to 0.5 per cent in South Carolina. Comparable variation exists in the percentage of local government revenues collected from property taxes.

Although property taxes have become relatively less important, their role as the distinctive local tax has resulted in extreme pressure to increase the property tax yield because of the increased demand for local services brought about by the rapid increase in urban population, especially in the number of school-age children. Although the demand for public services and property tax yields have increased, property tax payers have energetically sought to reduce their taxes through political action.

One way to reduce the property tax has been to introduce other financial sources, and these will be discussed below. Another way has been to limit the freedom of the local government in the use of the tax. This has taken the form of rate limits imposed by the state governments and of an erosion of the base through exemptions and poor administration. The property tax payer has been able to utilize his political power in the state capital to restrain local finance in one direction, but this has resulted in tax expansion in other directions.

Another political response to the increase in property taxes has been the adoption of fiscal profitability as a criterion for many local public policies, such as zoning, subdivision control, public facilities planning, and annexation.

In considering alternative land use developments, the local authority's analysts compute the property tax yields and the public expenditures associated with each alternative and then adopt the alternative with the maximum difference between property tax yields and public expenditures. Sometimes the analysis is more sophisticated, involving consideration of all the revenues to the local government and all the local expenditures requiring local finance. The results of the analysis almost always show low fiscal profitability in residential use by low-income families with school-age children and high fiscal profitability in industrial use requiring few transportation services, or in residential use by high-income families with few children. The outcome might be to encourage the development of clean industry and the residence of its executives and to discourage the workers employed in the plants from living in the area. Competitive behavior by all of the localities in the area would be self-defeating; on the other hand, if only a subset of the local governments adopted the criterion of fiscal profitability, then the entire area would develop inefficiently. Workers would travel longer distances, industry might not be optimally located, and so on.

The separate tax base does have the virtue of encouraging independent government, and certainly it has permitted American local government to be viable; but it has meant some loss in the efficiency of the operations of metropolitan areas. Although this separate (property) tax base is not likely to disappear, its role will decline because of the many defects of the tax per se and because of the endemic difficulties of independent financing of local governments. [See *TAXATION*, article on *PROPERTY TAXES*.]

Shared bases with separate levies. Two types of base sharing are practiced. One form is that of complete independence between the levels of government; the bases need not be identical and the rates are independently determined. In the second type the base is identical, although rates may be independently determined, and often there is common administration. Both types are common in all nations.

An illustration of complete independence is the income tax. Although this is usually considered a central tax, many localities use it as well. In the United States in 1964, it was used by two-thirds of the states and by 30 cities. Although the states may

define their base so as to approximate the federal base, the local income taxes tend to be payroll taxes. Because its narrower base gives rise to charges of inequity, the local income tax is not likely to be used widely.

A more common form of sharing of bases is under some joint administration, either restricted to the definition of the base or extending to collection. The property tax takes this form within the structure of local governments and in some countries is shared by local and national governments.

In the United States property may be appraised by the state or county, and each of the hundreds of local governments may then independently determine the rate it requires to satisfy its revenue requirements. In some cases a common appraisal of the property is required, while in others it is simply economical for one community to accept the appraisal of another. In either event, the set of taxes may often be collected in one bill and then allocated among the governments.

Although this procedure does limit the power of the government to determine the base most advantageous to it, it has the advantages of uniformity and administrative efficiency while allowing each local government to determine the level and distribution of services it prefers.

A somewhat more centralized tax shared by state and local governments in the United States is the general retail sales tax. Over two-thirds of the states have retail sales taxes, and several thousand local governments add tax supplements onto the state tax. There is a marked trend to adopt this tax structure, with administration by the state or local government and local government option to share in the base. Generally there is a ceiling on the local supplement, and sometimes a specific amount is stipulated. Under this structure the local government has formal freedom, but the incentives for all local governments to develop a uniform policy are great.

The trend has been to move from overlapping taxation of a common base, with independent definition of the base and rates, to joint definition of the base and common administration, with independent rates, and then on to more restrictive rules about rates.

Shared taxes. A shared tax is simply the transformation of a local supplement to a national tax into a simple assessment of the tax by the national government, with some share going to the local governments. This scheme is fairly common throughout the world, though of relatively less importance in the United States. Generally the transformation has taken the form of extending state administration of the tax, returning some of the

proceeds to the local government which had been using it, e.g., the development of state motor-vehicle license taxes out of local personal property taxes assessed against automobiles. The initial impetus to shared taxes was the desire to achieve simplification and uniformity, but rules of sharing have become increasingly complex. Issues of need have been introduced into the formulas, so that it is often difficult to distinguish between a shared tax and an intergovernmental grant. Although, in principle, these two forms of financing are very different, experience has shown that if the central government has authority over the sharing formula, it will exercise its discretionary power and the local government will lose control over the size of its budget and sometimes even over the use of these shared funds.

Intergovernmental grants. The most completely centralized form of local financing is tax assessment and collection by the central government, with a transfer of funds to local governments for financing their services. This type of finance has grown most rapidly. Control over finance does not logically entail authority over local public services, but experience has shown that this has been the usual result. Generally, the three preceding forms allow fairly complete freedom to the local government in the allocation of its budget and often in determining the size of its budget. But even if no financial controls are exercised by the central government, localities may not have autonomy, since in many nations local governments are required to provide specific services which sometimes are prescribed in detail.

There are two general types of financial transfers from central governments, basically distinguished by the amount of discretion which remains with the local government in the allocation of the funds at its disposal.

Unconditional grants. The free unconditional grant in its purest form would be a simple transfer of funds from the central government, which is considered the most efficient taxing body, to the local government, which is considered the best decision-making body. If the problem confronting local government were simply financial, one would expect to see these unconditional grants play a major role. In fact, their role is trivial. Few countries use them, and where they do exist, as in England, they are not a major factor in local finance.

Local government has long advocated that grants be made as unconditionally as possible, in order to retain as much local autonomy as possible. But even where only minimum conditions are accepted as desirable, redistribution objectives are introduced into the criteria by which the grants are allo-

cated among communities; and these originally very broad redistributional objectives readily become more specific and thereby influence the quality and types of public services to be encouraged.

Conditional grants. Conditional grants to local governments carry with them specific requirements for local government behavior. Since the conditions must be policed, extensive audit procedures accompany the grants. Local governments generally oppose this form of support, since they dislike the administrative supervision by the central government and they oppose its direct control of their budget.

The motives behind conditional grants are many. In some cases, especially that of the United States, it is not politically feasible to establish a central administration, but the same results are sought through imposing very specific conditions. Two other important motives are the encouragement of specific services and financial equalization.

The encouragement of specific services is obvious when the grant does not require the local government to contribute to the support of the service. Some local governments might deplore that the grant is directed toward their less urgent needs, but at least it will not divert their resources. But often the condition of the grant requires matching outlays from the local government. Since the local dollar spent on the subsidized service will buy proportionately more of that service, it is clear that budgetary allocations will be affected. There will be incentives to expand local support of the subsidized services. This budgetary distortion has been resented by local authorities. The encouragement of specific services through local matching provisions has become less important.

Financial equalization has become more important. Although this objective was never absent, initial matching grants were more favorable to the wealthier communities. More complex formulas have since been devised to take into account local needs, local fiscal resources, and local fiscal effort. Despite the increasing sophistication and complexity of formulas, no consensus has developed about an optimal formula. Subsidies distort; their administration will be lax if there is no burden on the local government; and if a burden is imposed, then the localities may not have the appropriate incentive to expand the service or equity may not be served.

Financing of local debt

Another aspect of local finance which has dramatically changed in many countries is the financing of local debt. Even in the United States, where a local government usually goes to the capital mar-

kets very much as private firms do, changes have occurred. Not only have debt limits become common and referendums by the voters often required, but the approval of a state agency as to technical or financial feasibility of the project now is often required. A further change has been the growth of loans by the central government to the local governments. In some countries almost all loans are centralized; in the United States the loan program is one of the instruments of intergovernmental transfers. The loan is often administered by the agency which administers the grant program and which may be carrying on services as well. State governments also extend loans to local governments.

Although the centralization of government and finances has been the most important recent structural change, another reorganization, concerning metropolitan government, may be of comparable importance, especially in the United States. A typical metropolitan area is made up of hundreds of governments. Some are the residuals of an agricultural economy of a half-century past, others are the many new suburban cities, and still more are the special-function governments ranging from a small-area police district to a regional air-pollution control board. Most of them have taxing powers, while some can finance themselves only by user charges. The conflicts among these governments have focused on the suburban-central city rivalry for financial bases. Central cities have charged that suburbanites work in the central cities and use all of their amenities while living in the suburbs, where they pay their local property taxes. The suburbs charge that they bear the heavy burdens of education and residential services while the fiscally rich industrial and commercial properties are in the central cities or industrial enclaves. Issues of equity in finance and service have inhibited agreements about urban development programs, and meanwhile the government of the metropolitan area has deteriorated.

The problems of metropolitan government and finance have been elaborated in great detail. Solutions have been of an *ad hoc* nature, e.g., a federal subsidy for urban renewal, a new government for a mass rapid-transit system, or an additional tax base. Despite the muddling-through procedures, there has been a great deal of experimentation.

In the past decade, user charges have increased sharply at the state and local levels. The metering of water and on-street parking has expanded as a revenue source, and the value of user charges as rationing devices is beginning to be understood. User charges not only help to bring about an effi-

cient rationing of limited public services, provide cues determining the scale at which services should be performed, and ease the financial plight of cities, but also lessen the conflict among governments. For example, if there is a charge on visiting the museum, it is irrelevant whether the school bus is discharging suburban or central city children; either school district would have to pay for cultural enrichment. Or it is unimportant if the parker is from the suburb or the central city if he pays the full incremental cost of making the street space available for his parked car. It is very likely that there will be a significant expansion of pricing of public services over a wide range of activities. [See PRICES, article on PRICING POLICIES.]

Innovations in local government arrangements have occurred in response to crises: many special authorities without taxing powers, or districts with taxing powers which move freely across old jurisdictional lines, have been created. From one perspective the *ad hoc* responses to crises have generated another layer of bureaucracies and assessing agencies, complicating still further the problems of rational management. But these governments are very fluid, their political bases are weak, and the possibilities of a more deliberative reshuffling of government and financial structures are not trivial. Metropolitan governments may develop out of the array of municipal governments and overlapping special districts and authorities, but it is likely that the state and federal governments will be the prime movers in metropolitan development and that the financial base of the metropolitan government may look very different from that of a mere composite of existing local governments.

LOCAL GOVERNMENT

Local government may be loosely defined as a public organization authorized to decide and administer a limited range of public policies within a relatively small territory which is a subdivision of a regional or national government. Local government is at the bottom of a pyramid of governmental institutions, with the national government at the top and intermediate governments (states, regions, provinces) occupying the middle range. Normally, local government has general jurisdiction and is not confined to the performance of one specific function or service.

This simple definition obscures wide variations in local governmental systems and operational patterns, and it should be supplemented by a system of classification for both description and analysis. In the past, local governments have been classified largely in terms of their formal structures. Thus, in the United States great stress was laid on the question of whether a local government had a mayor with broad executive powers or a mayor who was little more than a presiding officer of the city council (the strong versus the weak mayor "plans"); whether the council members divided among themselves administrative responsibility for the several aspects of local government (the commission plan); or whether the council employed a profes-

sional executive agent to administer the city's affairs and be accountable to the council (the city manager plan). Similar emphasis was placed on form and structure by authors attempting cross-national comparisons of local governmental systems. A perusal of the publications of the International Union of Local Authorities (e.g., *The Structure of Local Governments* . . . , Humes and Martin 1961) or of the contents of *The Municipal Yearbook* will indicate the dominant concern for structure. The *Yearbook*, for example, provides details on the organization of local government, but only in 1963 did it begin to provide data on local elections.

The formal structure of local government, important as it can be to the character of a system, is not the only nor even the most significant determinant of the style of local government. The quality and character of a local government are determined by a multiplicity of factors—for example, national and local traditions, customary deference patterns, political pressures, party influence and discipline, bureaucratic professionalism, economic resource controls, and social organization and beliefs. That a local government is located in a nation controlled by a communist party may be an infinitely more important fact than the structural forms it has. That an American city is located in the South, where Negroes occupy an inferior social position, may explain far more about the local government than its structure. The existence of a huge economic enterprise within a given municipality may be more determinative of the style and policies of a local government than its organization. And, it might be added, this may be as true in a totalitarian regime as in a democratic one.

There are hundreds of thousands of local governments in the world, and we lack sufficient information about their operational characteristics to make completely confident generalizations about the nature of local government or to isolate the most critical variables that shape it. In the process of moving toward surer understanding of the phenomenon it is useful to pursue answers to three basic questions about any local government. First, to what extent is there local self-government? For example, do the people of the community have an opportunity to participate in government through meaningful elections and to have access to public officials to express their opinions by organized and individual activity? Second, to what extent does the municipality have relative autonomy and discretionary authority to act? That is, is there a *de-concentration* of authority from the central government to the locality with little or no local

discretion, or is there *decentralization* of authority with relative discretion to undertake programs on local initiative and with relative freedom from strict supervision and restriction from the central government? Third, is the local government a vital and significant force in the lives of the people? Is the government an institution with the will and the authority to undertake activities that deeply affect the lives of people, or is it so marginal an aspect of life that the citizenry is scarcely aware that it exists?

To facilitate discussion of local government in terms of these broad questions, five broad categories of local governmental systems may be postulated: (1) federal-decentralized, (2) unitary-decentralized, (3) Napoleonic-prefect, (4) communist, and (5) postcolonial. The meaning of each category will become clear in the discussion.

Federal-decentralized systems

Those federal systems which decentralize much authority to the regional governments that compose the federation also tend to be the nations that allow the broadest range of discretionary authority to local government. This is not true of all systems that are called federal, however, but only of those with actual decentralization. The Soviet government is formally organized along federal lines, but such decentralization of authority to the districts as exists occurs under strict central government controls; it is made abundantly clear that the subunits of the Soviet system (the "republics" and their subdivisions) are in reality agents of the central government and the Communist party. In federal systems with much decentralization (for example, Australia, Canada, Germany, Switzerland, and the United States) the degree of autonomy of local government varies considerably from country to country, but in all cases a considerable degree of local independence prevails.

This variation extends deeper than the country-by-country comparison, for there is often much variation among individual states or provincial-regional governments as to the forms and authority of local government. For example, the closeness of supervision by administrative agencies of regional governments varies widely from fairly extensive reporting and oversight to almost none, except in cases of flagrant corruption. Likewise, certain states in the United States grant "home rule" to municipalities by statutory or state constitutional provisions that permit municipalities to alter their forms of government at will and that grant local authority to "make all laws and ordinances relating

to municipal concerns," or broadly the "powers of local self-government," while in other states the municipality has to appeal to the state legislature for specific permission to undertake a particular program.

The idea of "home rule" as local independence is an ancient doctrine, but as a legal concept it originated in the late nineteenth century when American state legislatures interfered, often corruptly, with the functioning of local government. Gradually, home rule has extended, with varying degrees of effectiveness, to most of the states. Home rule does not grant total autonomy by any means, since legislatures through general law and the courts through interpretation still restrain local government. Nevertheless, the concept contradicts the principle of municipal inferiority that previously stood as a basic rule of law. In the late nineteenth century Judge John F. Dillon stated the classic principle of the status of the local government by saying that municipal corporations were completely creatures of the legislature which could control or even destroy municipalities at will. In the famous Dillon's Rule he stated:

It is a general and undisputed proposition of law that a municipal corporation possesses and can exercise the following powers, and no others: First, those granted in express words; second, those necessarily or fairly implied in or incident to the powers expressly granted; third, those essential to the accomplishment of the declared objects and purposes of the corporation—not simply convenient, but indispensable. Any fair, reasonable, substantial doubt concerning the existence of power is resolved by the courts against the corporation, and the power is denied. (Dillon [1872] 1911, vol. 1, sec. 237)

American courts no longer follow Dillon's Rule rigidly, although its fundamental precepts are still frequently drawn upon even in home rule states, when local and state jurisdictions are in conflict. Litigation and the threat of litigation are important restraints upon local independence.

In the United States all local legislative bodies and most chief executives are directly elected. Local government organization varies enormously—from the town meeting, where all registered voters may participate in basic decision making, to the highly bureaucratized governments of many large cities where mayors combat the inertia of professionalism and pluralistic stasis (see Sayre & Kaufman 1960; Dahl 1961; Banfield 1961). In some cities powerful political party machines control decision making by the formal officeholders; in others business elites have great power; in still

others authority is widely dispersed to independent boards and commissions which are relatively invisible to the voters and partially beyond the control of the council or the mayor (for example, Los Angeles). Although it has commonly been thought that American small communities are highly democratic in the sense that the public has easy access to and much control over their representatives, research on local governmental operation suggests that this is not necessarily true (see Vidich & Bensman 1958; Presthus 1964). For example, survey research in American cities concerning the citizen's "subjective competence" (that is, a person's belief that he can exert significant influence upon his local government) indicated that two-thirds of the respondents felt a high degree of confidence in their political effectiveness, but there was no evidence of significant variation in terms of the size of the community from which the respondent came. Indeed, insofar as there was a variation, it favored the larger as opposed to the smallest cities (see Almond & Verba 1963, p. 235).

Swiss municipalities also have a wide area of local autonomy, although there are variations among the Swiss cantons (states) in this respect. The German-speaking cantons usually permit more discretion than do the Italian- and French-speaking ones. A high degree of local self-government prevails, particularly in the rural communities; in nine out of ten communes the municipal deliberative body is an assembly of all electors. In larger municipalities elective councils are employed, and under certain conditions a referendum may be used to submit questions to the vote of the people.

Other federal systems permit somewhat less local autonomy. In Australia, for example, local actions are subject to review by the state governor and ordinances are effective only after their approval by the governor, although there remains a general autonomy for the locality within the limitations of its local charter and the supervision of the state departments of local government. In Canada a considerable sphere of local autonomy exists, but not as much as traditionally prevails in the United States or Switzerland. An illustration of this is found in the decision of the provincial legislature of Ontario to form a new unit of metropolitan government in the Toronto area in 1953. The premier of Ontario warned that the legislature would act if the local communities failed to create some orderly method of coping with the problems of the metropolitan area, and when no action followed the legislature created a new governmental unit covering both the center city and its suburbs. While such

action would be legally feasible in most (although not all) states in the United States, American political traditions of local independence make it nearly impossible to do this.

The local government system of the West German Federal Republic also has variations in local powers and procedures among the provincial governments (*Länder*), yet the over-all independence of local governments is considerable. The degree of independence does not match that in the United States or Switzerland, however. The burgomaster (roughly equivalent to a mayor) is a professional administrator and occupies a very strong position in the local government; significantly, he is not only a local official but a federal and state official as well, since the city performs certain functions for the higher jurisdictions. The supervision of local government from higher echelons is also fairly rigorous, and this has increased as the practice of the state's delegating certain functions for local performance has grown. It is perhaps suggestive of the representativeness of German local government that a far higher proportion of German respondents to an opinion survey indicated that they believed they could "do something about an unjust local law or regulation" than those who felt any competence to correct an unjust national law (Almond & Verba 1963, p. 185).

The vitality of local government in the federal-decentralized countries varies both within and among countries. In the United States the role of local government expanded greatly with the maturation of industrial society in the first half of the twentieth century; protective, regulatory, welfare, planning, economic promotion, cultural, and other activities were initiated or expanded. But the extent of expansion varies greatly with the size of the city, the area of the country, and even for adjacent cities. In the largest cities, where the functional expansion has been greatest, the hugeness and impersonal nature of the government probably make government appear to impinge less on the lives of the citizens than it does in fact. In smaller rural or suburban communities, local government ranges from the moribund to the fairly vital. Likewise in other nations the degree of vitality and impact of government varies widely. In the Swiss communities where a town-meeting style of government prevails, the sense of involvement and the level of participation are high. The English-speaking Commonwealth federal systems appear to have a range of variation in the vitality of local government that compares generally with that in the United States. [See *FEDERALISM*.]

Unitary-decentralized systems

Great Britain and the Scandinavian countries are examples of nations with unitary (that is, non-federal) governments which have a considerable degree of decentralization of autonomous power to localities. Although in all cases there is supervision by the central government, and although localities can take only such actions as authorized by the central government, local governments in these nations do have fairly wide responsibilities and make independent decisions about them. The independent status of the English city has a long history, as evidenced by ancient royal charters of cities. The first charters were just agreements by the king to recognize certain concessions that local leaders had bought or bargained for, but in time the charters became regularized and the basis of a considerable area of local discretion. As early as the fifteenth century merchant guilds and borough councils originated the rudiments of local self-government. Parliament remains the supreme source of local authority, but the practice of permitting local prerogatives is so firmly established that curtailment is always resisted and comes only after great deliberation. Nevertheless, there has been a considerable diminution of local independence since the nineteenth century. Although the functions of the municipality have in some respects been enlarged with the coming of new problems and public policies to meet them (for example, public housing), an extension of the central government's concern for formerly purely local matters has taken place simultaneously. Particularly in the fields where the central government has provided a percentage of the cost of programs through grants-in-aid, central government departments have greatly extended their control over local decisions. Centrally established minimum standards of performance have unquestionably raised the efficiency of local government, but at the same time they have curtailed the independence that once existed.

British local government is representative self-government. The local council is directly elected, although the local executive is not. The mayor (or chairman in certain local bodies) is chosen from among the council members, but he is not the chief executive in the same way that an American mayor is. The British mayor is more a ceremonial and presiding official than an active executive leader, and to the extent that he is the latter it is the result of his personal qualities or his political position. The major operating element of the British local council is the committee system, into which noncouncil members are co-opted as experts on

aspects of policy covered by the particular committee. Although the council must ratify all committee actions before they are valid, the committees are the active elements in the process rather than the council as a whole. The town (or county) clerk also plays a significant role in local government in his relationship to the committees. It is he who prepares information for the committee and sets the agenda, but he is not a British parallel to the American city manager, for he is not directly given the function of overseeing administration. Traditionally clerks are not trained in administrative management but in the law, although their apprenticeship in local government necessarily emphasizes administrative matters, and as the problems of local government become more complex it increasingly falls to the clerk to provide expertise and to coordinate the diverse elements of local government.

Since the early nineteenth century local governments in the Scandinavian nations have been allowed a fair degree of autonomy. The list of powers for local government is extensive, and while regional appointees of the central government who are in some respects similar to the French prefect oversee local operations, the actual supervision is not strict and does not compare with that in nations with prefectorial systems. In Norway all actions involving expenditures must be cleared with the provincial governor before they can be carried out, which on the surface suggests that Norwegian local government may be less autonomous than that of Britain. In fact, however, Norwegian municipalities have somewhat more discretion, since the supervision is not strict. Norwegian local government is vital, has broad scope, and is a very important aspect of the nation's political-governmental system. Local government is a common recruiting ground for higher political office, and local forms and practices have been used as modes for creating regional institutions and practices. Denmark also has close supervision of fiscal matters, but the check on local government that this might imply is not apparently onerous. Local government is democratic, has a fairly wide range of discretion, but is somewhat less autonomous and vital than Norwegian local government. In Sweden local government activities are divided between those that are "free" of supervision, except on legal challenge, and those that are "regulated." Generally speaking, the free functions are those concerned with municipally provided utilities and cultural-recreational activities, whereas the regulated ones include a long list of functions extending from welfare services to town plan-

ning, local courts, and school administration. As in Norway and England there is extensive use of committees of the council for conduct of business. Finland's local governments have somewhat less discretionary authority and are subject to closer supervision, but the general pattern appears to be not markedly different from that in other Scandinavian nations. [See PARLIAMENTARY GOVERNMENT.]

Napoleonic-prefect systems

The peculiarity of this style of local government is that the central government places in subregions of the nation an agent of the national government to oversee, and if necessary to countermand, suspend, or replace local governments. The system is a direct survivor of the ancient institutions by which France attempted to create a centralized nation out of a scattered system of feudal fiefs, small cities, and ecclesiastical domains. The office of *intendant*, conceived by Richelieu in the early seventeenth century, was a means of extending the king's authority into the hinterland, where the thirty *intendants* were known as the "thirty tyrants." Animosity toward the office resulted in its dissolution in the French Revolution, but Napoleon restored it as the office of prefect, and it still flourishes in France today. In varying forms the office is commonly found in southern Europe and in Latin America, just as British forms are found in English-speaking nations.

In France the basic unit of local government is the commune, of which there are some 38,000, and each is under the supervision of a prefect of a *département* (of which there are 90) or under the intermediate control of a subprefect of an *arrondissement* (more than 300). (In some areas superprefects also provide regional supervision.) The commune is typically a small community, since most of France is rural, although cities are also organized as communes. There is a high degree of local interest in commune politics, and council elections are often heatedly contested. The mayor, who is chosen from the ranks of the council, has a wide range of executive authority; and although he is legally accountable to the council, he nevertheless is a powerful political force in the municipality. Initiative in fiscal matters and other policy issues is in the mayor's hands. The mayor and the council operate under the eye of the prefect or subprefect, however; and all commune actions are subject to review by the prefect, who may refuse to approve or may even dissolve the local council or remove the mayor. There are, on the average, some three hundred dissolutions per year,

although a major cause of this is irreconcilable disagreement within the council rather than conflict with the prefect.

It should not be assumed, however, that French local government is actually controlled from Paris. Prefects and subprefects have a considerable area of discretion, and they often find it wise to strike a political balance between themselves and the mayors, who are not entirely without weapons to deploy against a demanding prefect, for national political forces are often just barely beneath the surface of local politics. Many mayors are influential national political figures, and local politics is a common basis for a political career. Despite this countervailing force against centralization, local government in France remains far more subordinate and dependent than in such countries as the United States and England. Police and education, for example, are largely beyond local control; fiscal controls and subventions are deployed by prefects to bring commune policy in line. Interest and participation, however, run high in France. A British observer, granting that in England local government had more autonomy than it does in France, nevertheless found in France more interest in local matters and more vitality in local government (Chapman 1953, p. 221).

In other Mediterranean countries and in Latin America, where the prefectural system prevails, there are many variations on the French pattern. In Spain and Italy, for example, there is considerably more centralization than in France. In Spain central government controls are rigorously applied to the more than nine thousand municipalities; the mayor is appointed by the central government, and he is the strongest force in local affairs. Portugal has a similar system of central control. In Italy the prefectural system was a convenient device for extending the powers of the fascist system into the hinterland, and interestingly one of the consequences of the fascist interlude is that the prefect has greater power today than in the prefascist era (Fried 1963, p. 261). Local councils are popularly elected, but the mayor and the councils are well aware of the power of the prefect, who uses his position not only to provide general administrative supervision but to pursue political objectives as well—such as the curbing of the power of communists when they take over a local government. In rural areas particularly, local government is not a vital or popular institution; it is often considered by the people to be an element of nature to be endured—like drought or disease—not something from which benefits are likely to be derived.

In Latin America extensive supervision of local

government by officials similar to the prefect is common. In some countries the local mayor is appointed by the central government, and in others he is elected, but his actions and those of locally elective councils are subjected to extremely close control by the central government. Brazil, with its federal system, does not conform to this, however, and it has relatively little central or state government oversight of the details of local government operations. An essentially prefectorial system is also used in Japan, where, significantly, a large measure of the authority of the supervising administrator lies in his discretionary authority to grant subsidies to local government.

Communist systems

The local governmental systems of communist nations are, in general, examples of deconcentration of authority rather than decentralization. That is, the local governmental unit is an agency of the central government, and it functions as an integral element of the hierarchical administrative system of the state. The area of local independence is narrow and extends only to minor matters, whereas control devices are extensive and are rigorously applied. Local officials are well aware that their decisions must conform to an over-all design of higher authorities, and they know, too, that to divert budget funds to other purposes without permission may mean dismissal or even imprisonment. These systems are unique in that local governments are given a role in economic activities infinitely more extensive than in capitalist nations. Finally the discipline of the Communist party is a means of controlling policy in detail. As a supplement to and a check on the administrative system, the Communist party with its rigid discipline controls the key positions in government. Indeed, the Communist party's role is remarkably similar to that of the classic American local government party machine. Where a classic American machine acquired complete control, the formal distribution of authority was unimportant; what mattered was the internal discipline of the party through which decisions were made from the top to the bottom of the government (McKean 1940). The critical difference between the two situations is that the American boss system depends upon local insularity to maintain control, whereas the communist system utilizes the local party to carry out the program of the national party leaders.

Local government in the Soviet Union is subject to very intensive control, but the minute and stifling controls of the Stalin era are no longer used. The ponderous apparatus needed for detailed supervi-

sion of local operations from Moscow became so expensive and inefficient that in the 1950s efforts were made to decentralize to a limited extent. In the 1930s the rigidity of controls was such that a local bakery's request for a supplemental flour allotment was passed to higher and higher authority until it finally reached the desk of the premier, and he approved the request himself (Granick 1960, p. 162). Documents captured by the Germans in 1941, in the town of Smolensk, also reveal the manner in which the party was used to assert tight control by Moscow over local operations (Fainsod 1958).

The decentralizing tendencies of the 1950s and 1960s did not necessarily increase the degree of local self-government. As before, the locality elects large local soviets in which there is much discussion of local affairs, but apparently the decision-making power remains with the executive committee of the soviet rather than with the soviet members themselves. Local leaders are, however, permitted a wider range of discretion for which ultimately they are held responsible to their superiors. Evidence that the new policies did not involve a total change is the story in *Pravda* following the departure of Khrushchev from power. Khrushchev favored reinforced concrete blocks over bricks for construction and, as word of his attitude filtered down the hierarchy, local managers shut down brickworks regardless of local demand. Khrushchev's successors promised in *Pravda* to grant to local soviets power to "decide all local issues"; if this becomes a reality it will involve an enormous change in the traditional balance of political power in the U.S.S.R. [See COMMUNISM, article on SOVIET COMMUNISM.]

The Chinese commune is a striking experiment in devising local institutions to serve the purposes of a dedicated communist regime. The communes are at once instruments of economic planning, educational and cultural activity, and governmental control. In order to increase manpower, women are freed from child care and household work through provision of nurseries, common eating facilities, and "service centers" for clothing repair and other household chores. Millions of Chinese eat in public mess halls in both agricultural and urban communes. Local marginal industries are organized and operated by the commune. It is claimed that more than 500 million Chinese were in communes in 1960, but this probably includes many paper organizations. Nevertheless, the commune is potentially an impressive device in its totality of involvement of the citizen's life, the opportunities it offers for political control through propaganda, police,

and tight party discipline, and its potential for economic production where man power so greatly exceeds all other forms of capital. It is an attempt to resolve China's age-old problem of balancing local initiative and central control—this time consistent with the requirements of an industrial revolution under rigid totalitarian control.

Yugoslavia offers a significantly different kind of communist local governmental system. Although the party and its discipline remain an important control factor, it is evident that a great degree of decentralization has been introduced. The Yugoslav commune has a bicameral council, one house being a political body elected by area and the other concerned with economic matters and representative of workers and farmers in their respective work units. The economic chamber is somewhat less powerful than the political one, since it acts on a more restricted range of issues; but on all basic economic questions, including the budget, the two chambers must agree. The central government has basic responsibility for the economic growth of the nation, and it grants funds for economic investment; yet the locality has some discretion about the form of development it desires and relative independence in the conduct of local enterprises once established. The municipal council sets basic standards of operation for all municipal economic organizations, and it appoints their managers; but the workers in the enterprises and their elected representatives have control over some aspects of operations. In addition to the workers councils, numerous other elected bodies deal with a broad range of subjects from education to social security. Periodic meetings of all voters who wish to participate allow for discussion of current questions, and under certain circumstances a referendum is possible, although it has been little used. In comparison with other communist systems, Yugoslavia has a high degree of decentralization and vitality. Local discretion and self government are, however, circumscribed by the existence of the party as a "guide" for local action. Yugoslavian leaders stress the importance of local self-government but at the same time emphasize the importance of the Leninist principle of "democratic centralism," which holds that minority views should give way to strict party discipline when basic decisions have been made. [See COMMUNISM, article on NATIONAL COMMUNISM.]

Postcolonial systems

The creation of new nations from former colonies involves varying degrees of change in local government. In some cases the imposition of a

strong single-party political system subverts old patterns almost entirely; in others, where adjustment more than revolutionary change has been the theme, local government patterns have not altered drastically. The legacy of colonialism is omnipresent, however much the new leaders strive for complete breaks with the colonial past [see COLONIALISM]. The pre-existing systems of local government, closely supervised by colonial officials and native subordinate administrators, have often remained as the general pattern of local-central government relationships. The terminology and basic structures of the colonial local government system frequently persist for reasons of habituation and convenience, if no other. Some leaders of postcolonial nations do not have a simple alternative of returning to a precolonial local government system, both because the colonial powers undermined or abolished the old ways and because the old systems were incapable of dealing with the conditions of Westernized and modernized life. The original tribal and village systems or bureaucratized empires of the past were appropriate to a rural, self-sufficient, and isolated kind of social life or to conditions of minimal central control; but as these nations become urbanized and begin to develop integrated economies, the simple forms of the past are inappropriate. Although some of the ancient forms of tribal rulership were allowed to continue by some colonial powers, it was apparent to local residents that the real authority rested not with the traditional chiefs and elders councils but with the administrators, both native and colonial, who supervised local operations. Not the least important of the remnants of colonialism, then, is the simple continuance of the great authority of the outside supervisor; the creation of active local democracy is difficult under any circumstances but the more so when habits of central supervision are generations old.

Local government in these nations is beset by staggering social and economic problems. In the first place, many of the cities of Asia and Africa are not cities in the European sense; they lack the technology, organization, resources, and slowly developed institutions of the Western city and are often massive accumulations of squatters. Also, as new regimes the central governments tend to be politically unstable. Extraordinary poverty, severe difficulties associated with economic growth, and chronic overcrowding in the cities all produce a range of problems not faced in more modernized nations. For example, many Indian cities face a serious problem in dealing with the tens of thousands who perforce must sleep in the streets at night, and a common problem of the local Indian

city corporation is the prevalence of beggars who are organized into self-protective groups to defend their rights. Interestingly, in certain African cities the analogue of the American boss system seems to have developed, where local politicians cater to ethnic minorities and attempt to provide assistance to the city newcomers in exchange for voting support. Remoteness of local communities where transportation is difficult means that many parts of the postcolonial nations have a high degree of local independence through default—the central government being unable to assert its potential authority. A few Near Eastern nations have suffered for long periods from a breakdown in local and national bureaucracy so that local services are not rendered and a semianarchic confusion prevails.

Although modernization is gradually prevailing over traditionalism throughout the postcolonial world, conflict between modernists and traditionalists is endemic [see MODERNIZATION]. Tradition in religion and in social organization is the enemy of rational bureaucratization and the extension of power by the new political parties of the developing nations; it is a battle between an old man in a gilded chair (the tribal chieftain) and a young man in a swivel chair (Cowan 1958, p. vi). The virtual elimination of the tribal chief as a man of authority, as in Ghana, is one pattern; whereas the retention of chiefs as significant factors, as in parts of Uganda, is another (Burke 1964). Where political parties are extremely powerful, for example, in Tunisia and Ghana, the forces of traditionalism have been hardest hit—although traditional forms have a way of surviving, partly because they tend to rest on kinship relations that are basic elements of the social fabric. In Morocco, for example, orders from the central government to establish local councils to direct local affairs meant that a few dominant families selected their leaders as the new ruling body. Likewise, commands by the Israeli government to resident Arab communities to create local governing councils produced a council of family elders based on kinship patterns.

There is much conscious effort in the postcolonial nations to improve the quality of local government performance, but much of this involves assertion of controls from above to get local action. In Pakistan, for example, the central government in its Basic Democracies Order of 1959 established a system of local government for all of Pakistan and, outwardly at least, encouraged the growth of local democracy. Yet the control of local operations by the central government is very close, and one observer has found that in a given area no less than 85 per cent of all issues on local council agendas

were put there by communications from the central government (Rahman 1962, p. 31). Inevitably the patterns of local governmental development in the postcolonial societies differ greatly, but the needs for economic growth and the extension of new national power to the hinterlands and in the rapidly growing cities have the tendency to produce as much central control as the regime finds possible. As a general rule the patterns are more like those of Richelieu's France than of Jefferson's United States.

The role of local government

Paradoxically, local government in the twentieth century seems to expand the number of functions it performs at the same time that it faces increasing central government supervision and a narrowing of its independence. As the problems of large and complicated cities and metropolitan areas grow, at least to the extent that financial means to cope with the problems exist, the city has greatly extended its role. Cultural activities expand simultaneously with programs on housing, redevelopment, air pollution control, and the recruitment of business enterprises. Many of the most dramatic and important of these functions are financed in good part by grants-in-aid from higher level governments, thereby decreasing local discretion at least to some extent. Also the expansion occurs simultaneously with a narrowing of distances between the central government and the municipality as the means of communication develop and as areas once isolated economically and politically become an integral part of a national economy and political system. It is therefore sometimes difficult to say whether local governments in a particular nation are now more or less significant agencies of government than they were in a simpler age.

In the case of the smaller communities there is not much doubt that increasing centralization has affected their range of discretion negatively. Although the capacity of a central government to control tends to dwindle with distance for the simple reason that remoteness prevents control, the growth of rapid communication tends to undercut this source of independence. Likewise, smaller communities caught up in the sprawl of metropolitan growth suddenly cease to be independent units and become entangled in the complications of over-all metropolitan areas. This leads to the development of regional institutions that in some degree may supplant or at least supplement local government, and it also tends to force local officials into governing in part through negotiation with officials from higher levels of government and with those of

neighboring municipalities (Wood & Almendinger 1961).

Finally, it is important to note that the role of the municipal executive has grown greatly in the present century, owing to the same forces that have heightened the role of the executive in national government. The technological complexity of the problems being dealt with increases the power of the bureaucracy; and the diversity and diffusion of modern life also tend to lead to a stronger executive since, especially in larger cities, the chief executive seems to be the only functionary capable of controlling the bureaucracy, focusing public attention on key issues, and pressuring the various actors on the city scene to respond to the challenges a city faces.

LOCAL POLITICS

Politics consists of the process by which goods, services, and privileges are allocated by government or the rules are established for their allocation by other social institutions. Local government is a political subdivision of a national or regional government which performs functions that are culturally defined as being "local" in character, which in nearly all cases receives its legal powers from the national or regional government but possesses some degree of discretion in the making of decisions and which normally has some taxing powers. Local politics, therefore, consists not merely of local activities which relate to national political matters, but it involves a degree of choice to be made within the boundaries of the local unit of government relative to the selection of office holders

and the making and execution of public policy. These decisions are not necessarily made unilaterally through a local political system and its institutions. Often decisions are shared with other governments, and local political institutions and processes are commonly interwoven with those of neighboring localities and with regional and national political systems.

The patterns of politics at the local level are greatly varied. They assume a particular character in a particular locality according to the prevailing influences of ideology, social structure, and technology in the society. In primitive social systems there may be little in the way of recognized political institutions, but of those that do exist, the local political systems are often more important than the national so far as the typical citizen is concerned. In more complex societies, where governmental bureaucracies are specialized, where much is expected in the way of governmental functions, and where rapid means of transportation and communication exist, the activities and relative importance of local government become largely a function of ideology—the belief systems and traditions that condition the minds of a politically significant portion of the population. In some cases, as in Nazi Germany from 1933 to 1945, local government is of little importance; in others, as in the United States throughout its history, local government has been important in theory and quite important in practice.

In societies in which the concepts of change, "progress," specialization, or economic interdependence are little developed, local government is dominated by a politics of consensus. Traditional functions are accepted and honored. Politics may center largely on particular politicians, with the size and importance of personal followings determining political power. One of the functions of politics may be that of entertainment for the ordinary citizen who has little else to amuse him. Innovation is not expected from the local political process. The notions of ameliorating social problems or elevating the standard of living may be unrecognized or unaccepted concepts. African, Asian, and Latin American village societies tend to follow this pattern. Even in fairly complex, industrially developed societies, the dominant ideology in rural areas may call for this kind of function to be performed by local government. The village, in all societies, tends to have a politics based on face-to-face relationships, with the behavior of politicians tempered by considerations of the expectations of friends and neighbors.

In complex industrialized societies, local politics may be analyzed according to (1) images of the ideal function or goals of local government, (2) the degree to which local government is integrated with or insulated from the national political process, (3) the degree of autonomy of local government in relation to the national government in terms of discretionary powers in policy making, or (4) the distribution of power within the community.

Images of local government. The leaders in each community, irrespective of the amount of discretionary power vested in local government, seem to have an image of what the ideal community would be like and they seek to convert the image into reality. No one has attempted to develop a world-wide typology of such images, but some information concerning them is available. In primitive societies, the image is generally well established by a prevailing set of values and an absence of a desire for change: that which is—if uncorrupted by outside influences—is right.

In the United States, three types of images have been identified by Williams and Adrian (1963):

(1) Those designed to utilize government for specific policy goals constitute the first type; they can be divided into two subcategories, those with (a) production goals and (b) consumption goals. In the case of production goals, the common one in the United States is expressed in terms of "boosterism." The emphasis is upon public support for extending water supply, sewer lines, and other services into areas where industry or large commercial enterprises might locate, so as to help attract new jobs and broaden tax bases in the community. Land-use planning and controls designed to reserve sites for industrial parks, efforts to annex new territory suitable for industrial development, and special tax inducements for new industry are among the other attempts to lure new sources of wealth to the area and keep them there.

One special version of the production-oriented community is the "company town." This institution (in which the owners of a mine, lumber company, or factory own all property and businesses in the community) is disappearing in the United States. It so exclusively emphasized production goals or interests that it became unacceptable to the contemporary American culture. In some communities a single firm still dominates the local economy and takes a large part in social and political life. With the decline of locally owned industry and the dispersion of members of high-status "old" families, this pattern of *noblesse oblige* (and the develop-

ment by these elites of a unique community and one attractive to live in) has become much less common.

Since the end of World War II the residential suburb has been more likely to emphasize consumption goals, i.e., more of life's amenities provided by local government than by the central city; these include effective sewage systems, palatable water supplies, beautiful parks, quiet traffic, good schools, imaginative recreation programs, and ornamental street lights. To maintain life styles desired by the politically dominant, there is likely to be interest in a comprehensive community plan to help clarify and program goals, as well as in effective land-use controls. Emphasis is generally upon the professional administration of these activities, with the council-manager plan often the preferred urban structure.

(2) A second type of community image calls for local government to perform, at a minimum level, only those traditional functions that are viewed as strictly necessary for the community, such as education, police, fire, and water services. This approach, sometimes called the "caretaker" image, is often associated in the United States with a low-tax ideology. All over the world it is associated with traditionalism and opposition to industrialism and the breaking down of established life styles.

(3) A third image of the proper role of local government, never dominant in the United States, is that of an instrument for the administration of central government policy with no local policy making. This is the prevailing image in countries where strong central control over local government is traditional, as it is in France and in many Asian nations.

Probably no single image is held exclusively in any given community of a complex society, although in some cases one is clearly dominant. Where images compete for acceptance, compromise seems to be the ordinary result, with some concessions to each of them.

Insulation or integration. The politics of local government may be closely tied to that of national politics or may be quite independent. In many democratic (e.g., Great Britain) and nondemocratic nations (e.g., the Soviet Union), national parties are active at the local level. On the other hand, in some democratic nations (e.g., the United States) or nondemocratic ones (e.g., some African states), national political party activity may be sharply separated from local.

In European democracies national parties commonly include in their platforms proposals relative

to local government policies (although national and local elections do not necessarily coincide). It is assumed that politicians active at the local level are also committed to work for a national party. Whereas this is normal in European democracies, in the United States the pattern has been more complex. The American political arrangement in the last half of the nineteenth century was similar to that of European democracies. Political machines of that period were closely linked to national politics, and this remained the case past the mid-twentieth century in some cities, particularly in the East and in Chicago. But the reform movement that affected many communities, beginning in the 1880s or thereabouts, placed emphasis upon the separation of local from state and national politics. The result was a nonpartisan movement, based on the assumptions that local government issues are unrelated to the activities of national political parties and that the political aspects of recruitment for local offices should be reduced as much as possible. In the 1960s, even where party labels continue to appear on the ballot, it is common for local elections to be largely separated from other elections in terms of election dates, issues, and personnel. Parties continue to be important in most non-school-board and nonmunicipal elections and particularly in county and township elections. But because relatively few counties in the United States have meaningful two-party competition, even where the office seekers are active in a party, the real competition for office is often within a single party [see PARTIES, POLITICAL].

The amount of organization for politics at the local level has been declining in the twentieth-century United States and elsewhere. The great urban political machines that emerged during the period of rapid urbanization following the American Civil War were examples of near-complete political organization in a democracy. With their well-financed, ably led, city-wide party structure, they had ward, precinct, and block workers who looked after the party's interests and provided welfare services for party adherents. These machines achieved an intimacy concerning the problems, expectations, and political mood of constituents that rivaled that of the rural county and township machines, which also flourished during this period. [See POLITICAL MACHINES.]

The machines declined with the coming of alternative group associations (e.g., trade unions and ethnic and racial social and benevolent societies), middle-class reform efforts (especially to provide a secret ballot and accurate election results and to

mobilize those who once believed it was unavailing to "fight city hall"), a higher living standard for a greater portion of the working class, and the professionalization of welfare services, particularly after 1933. Local politics in the United States is today characterized by the presence of few professional politicians. Candidates are commonly amateurs, recruited (sometimes self-recruited) from business, labor, or the professions, often by groups of lay citizens who have banded together into a part-time political-action group. Some candidates are clearly the choice of, and spokesmen for, particular interests (realtors, builders, merchants, labor unions), and the current pattern seems to encourage such candidates more than did the political machines. The boss's brokerage concept of the role of the councilman or mayor was broader than the concept of the guardianship of some specific interest. Political communication at the local level remains more on a face-to-face basis than it does for politics in general, but radio and television have become important, especially in the larger urban areas. Much communication is through associations that are only in part political, such as labor union locals, neighborhood associations, chambers of commerce, farm organizations, church lay groups, and community councils. The leaders of these organizations are also important opinion leaders, for many ordinary citizens rely upon them as sources of political guidance [see INTEREST GROUPS; POLITICAL CLUBS].

Discretionary decision-making powers. The variety of local politics is accounted for in part by the political stakes involved in local decisions, and these vary according to the social significance of decisions that can be made at the local level. In some traditional societies local politics may involve no expectation that the actors will make decisions affecting the allocation of goods, services, and privileges. In nations such as France through much of its modern history, where powers are centralized but political parties cannot provide effective leadership, or many Asian nations where innovation is encouraged by the central government, local politics may center on actors who seek to protect traditional local standards and values against the views and policies of the professional national bureaucracy.

In some countries, such as Great Britain and those of Scandinavia, where political parties seek to tie the various levels of government together in a common move toward agreed-upon governmental service goals, local politics tends to be oriented toward the activities of national parties. Political activists, rather than civil service specialists, provide

the principal coordination in programs. In countries with a strong tradition of decentralized decision making, such as the United States, local politics combines showmanship, questions of relationships with national parties and state and national bureaucracies, and the settlement of many policy questions which are left to local governments by the states. Although the process of cooperative federalism, which has been developing for many decades in the United States, has reduced local autonomy in decision making, many decisions that affect the allocation of goods, services, and privileges are still made by actors in local political roles. As a result, the viewpoints of those who occupy particular offices are often important. But local politics is not necessarily on a higher plane in the United States because local government is a power center. The patterns of recruitment and contesting for office and of decision making may depend chiefly on whether or not there is consensus regarding the image of the proper policies for local government [see FEDERALISM].

The distribution of community power. A central problem in the analysis of local politics has been that of identifying the power holders. Studies designed to do this have generally ignored the question of how much power local governments actually are able to allocate (the amount available may, in theory at least, bear some relationship to the status levels of persons who become involved in the local political process). The concentration has been on identifying those who are wielders of power over whatever decisions can be made locally. By the mid-1960s questions of power were still of keen interest to social scientists, but many questions concerning its character remained unanswered. Among the issues the following were of critical importance:

(1) Is power deliberately used by an elite in a conspiracy to control society or is it essentially a socially useful device serving to provide an orderly social system? The conspiratorial theory stems from Marxian ideology and holds that a relatively few persons dominate local decision making for the benefit of the business and industrial leaders and middle-class citizens generally. In contrast, another theory holds that in a pluralistic democracy power may be distributed widely among various classes and groups in the community, with a variety of resources (e.g., money, votes, status, intensity of concern) as a basis for power. In support of the latter position, some have argued that the rising importance and numbers of functions of government have made the formal holders of elective office and the professional civil servants

powerful in their own right and not mere satraps for hidden leaders.

(2) Is the power structure monolithic or internally competitive? Early studies tended to find a monolithic pattern in which power holders met informally to decide policy relative to major items on the community agenda and to compromise any differences within the group. More recent studies indicate that power holders compete with one another, posing power against power, and negotiate with one another as diplomats and politicians. The concept of a "power structure," or simple pyramid of relatively powerful persons ranged in hierarchical order, is being replaced by that of a "power complex" of often competing persons from downtown businesses, neighborhood businesses, industry, organized labor, religion, education, politics, and sometimes other areas.

(3) Is power integrated or multinucleated? That is, are the power holders all in communication with one another, ordered in a single hierarchy, concerned with all major issues, and equally powerful in relation to all major issues? Or is power distributed functionally, so that those who have much to do with decisions about education policy, for example, overlap little or not at all with those in the fields of transportation, parks, or sewage disposal? Early studies (Robert and Helen Lynd in the 1920s, W. Lloyd Warner in the 1930s, and Floyd Hunter in the 1940s) tended to see an integrated structure. More recently, research reports indicate functional specialization, but whether the differences result from improved research techniques or from a changing distribution of power is not known.

(4) How are power holders to be distinguished from power users? A number of problems have arisen in efforts to identify those who are powerful in local politics. Some of these are problems of theory construction (Is a person powerful if his wants are anticipated and met even though he does not directly participate in a decision?); others are those of method (Can the powerful be identified more accurately by collecting and classifying the opinions of the supposedly knowledgeable or by observing the actors in particular decisions?). The study of local political power is complicated by the efforts of decision makers to anticipate the wants of those who are believed to be important or potentially powerful. It is also complicated, among other ways, by the fact that respondents and researchers have varying definitions and concepts of power and by the probability that a person asked to name the powerful cannot accurately identify them all and may overdiscount (or alter-

natively, exaggerate) the power of persons he disapproves of or regards as lacking a *legitimate right* to be powerful. In the 1960s research was continuing on the problem of analyzing local political power. Some of the most productive work in sociology and political science was taking place in this area [see COMMUNITY, *article on THE STUDY OF COMMUNITY POWER*; see also POWER].

Liberalism and conservatism. The concepts of liberalism and conservatism common in the Western world do not necessarily have the same meaning when applied to local politics as they do at the national level. The socialist, labor, and other reasonably well-disciplined parties of European democracies have tried to give the terms equivalent meanings at all levels of government. American national parties have not seriously attempted to bring local issues into their platforms or campaigns, and they have not themselves been clearly identified along a liberal-conservative continuum. In the twentieth century liberalism has become identified with the involvement of government in coping with a large variety of economic and social issues financed through a progressive tax system. While the social-service state has become the established pattern in the United States, home ownership has also become increasingly widespread. As a result studies have shown that persons who vote for liberal candidates for state and national offices may vote for conservatives at the local level, and vice versa. In particular, working-class homeowners with modest incomes sometimes oppose bond issues for capital outlays that would benefit them and vote for advocates of "caretaker" government, apparently because the cost of local government so clearly falls on the property owner. Sometimes they do this despite strong appeals for support of an issue or candidate by labor or other liberal leaders. Working-class persons have not pressed for social-service state and liberal reform programs (such as public housing or urban renewal) at the local level. Upper-middle-class persons, on the other hand, frequently are willing to spend local tax monies and subscribe to the images of "boosterism" and "amenities." As a result the terms liberal and conservative are often quite meaningless when applied to local government.

Local politics and democracy. Studies of local politics since the end of World War II indicate that the bulk of citizens in American democracy do not exert much individual influence, even at the local level. In fact, the pattern at the local level appears to be not much different from that at the national, despite the prevalence of nonpartisanship and the supposed significance of physical proximity to the

decision makers. The level of information possessed by the typical citizen is low, citizens take their cues from various political leaders, and decisions seem to be largely the product of bargaining among leaders. Voter participation at the local level is typically lower than it is for national and state elections, and some scholars have been concerned about the high level of alienation at the local level, although evidence as to the significance of this, if it exists at all, is inconclusive. The indifferent do, however, seem to move toward the extremes of the political spectrum when they become activated, just as is the case in national elections. In the 1960s, then, the study of local politics leaves unanswered some questions that are important for democracy. Particularly, it is still uncertain how much citizen participation is necessary for healthy democracy at the local level, what form this participation should take for the viability of democracy, or to what degree present systems of local government provide adequate or satisfying representation and access to decision makers by all segments of the local population.

LOCKE, JOHN

John Locke made important contributions in the areas of epistemology, political theory, education, toleration theory, and theology; he also wrote on natural law and on various economic topics.

Born in 1632 in a Somerset village, he was the eldest and ultimately the only surviving child of a family of tradesmen and small landholders. His grandfather had been a tanner and clothier; his father was a notary with landholdings later inherited by his son. He kept his connections with his ramified west-country family and friends, most of whom were Whigs throughout the turbulent years of the later Stuart rule. After living for many years at Oxford and on the Continent, Locke made his headquarters in Essex in 1691 with his friend Lady Masham; in 1704 he was buried among the Mashams in the village church at High Laver.

Intellectual development. Locke studied at the Westminster School and Christ Church, Oxford, where in 1658 he was elected senior student (the equivalent of a fellow in other colleges) and taught moral philosophy. His academic duties were always light, and he consistently sought to lighten them still more, especially after 1666, when he

met Lord Ashley (later Lord Shaftesbury), the great Whig leader; thenceforth Locke spent more time in London than at Oxford.

The political parliamentarianism of Locke's father may have influenced Locke's own ultimate Whiggery, which was strengthened by his association with Shaftesbury. Many west-country families, like Locke himself, became part of the "Shaftesbury connection" of Whigs, later supporting William of Orange in his successful coup. By all odds the most influential connection of Locke's life was with Shaftesbury, who quickened his early, though latent, interest in questions of political philosophy and practice. During his Shaftesbury years Locke sat on the Council of Trade and Plantations, an overseeing body for crown colonies, Ireland, and proprietary holdings in the New World. His interest in economic problems can be dated from that experience. Although he had been only on the fringes of the complicated politics of the late reign of Charles II, in 1683 Locke had to leave Oxford for good, a political refugee in Shaftesbury's wake.

Locke's intellectual development was marked by autonomy and autodidacticism. Evidently bored by his studies, he independently followed the medical curriculum at Oxford; though he never took his doctor's degree, he was qualified to practice medicine and did so, largely for the Shaftesbury family. He also studied chemistry in Robert Boyle's laboratory; in this way he came to know Boyle and eventually became an executor of his will. Other scientific friends were Richard Lower, Thomas Willis, and David Thomas; in 1688 he was elected a fellow of the Royal Society. Locke's "corpuscularianism," or atomic theory of matter, had much in common with Boyle's; his general curiosity and interest in "things" rather than in their names, as well as his experimental approach to social and scientific matters, can all be connected with his serious interest in the biological sciences. His medical empiricism was much like that of his associate Thomas Sydenham, one of the major experimental physicians of his day, who was especially interested in public health; both Sydenham and Locke voiced their awareness of the "unknowing," the "probabilism" involved in medical practice, notions which later influenced Locke's epistemology.

Locke's fear of Catholicism and absolutism had its roots in the English political scene and was deepened by several journeys to France, where persecution of the Huguenots was then intense. His Dutch sojourn, from 1683 to 1689, was voluntarily undertaken as a prudential flight from a government increasingly hostile to men of his political association and views: he was deprived of his

studentship at Christ Church and even put on a proscription list of James II's real and supposed enemies hidden in Holland. During that time, Locke met many congenial thinkers who in different ways reflected his own biases and concerns: among others, Arminian broad-church theologians, all theorists of toleration; medical men interested in experiment and learned in a tradition other than his own, that of Cartesian medicine; publicists dedicated to the diffusion of both learning and information.

When Locke returned to England in 1689, it was to a government of which he could approve; by that time he himself had become an honored man and was recognized as a major thinker. Thenceforward, he devoted himself to studying and writing, while holding minor government offices and occasionally conferring with political leaders.

Writings. From the early 1660s Locke had written many short essays, evidently for his own clarification, on natural law, on the civil magistrate, on toleration. In 1669 these preoccupations fed into Lord Shaftesbury's *Fundamental Constitutions of Carolina*, written with the aid of Locke. (Although this item appears in Locke's collected works—see *The Works . . .*, vol. 10, pp. 175–199—it has been established that Shaftesbury was the principal author.) Locke's *Two Treatises* (1690a) were written, as we now know, at the time of the Exclusion crisis of 1679–1681, when Shaftesbury unsuccessfully attempted to exclude the duke of York from succession to the throne because he was a Catholic.

While Locke was in Holland, one of his publicist friends, Jean Le Clerc, persuaded him to write for his periodical: thus, in the *Bibliothèque universelle et historique*, a fortnightly review of issues and books of international interest, Locke published some book reviews—among others, one of Newton's *Principia*—as well as original works of his own, the chief of which was his abridgment of the then unpublished *Essay Concerning Human Understanding* (1690b).

In 1689–1690 Locke began his serious publishing career: *A Letter Concerning Toleration, Being the Translation of the "Epistola de tolerantia"* appeared in 1689 (*The Works . . .*, vol. 6, pp. 1–58); the *Two Treatises of Government* in 1689, bearing the date 1690; the *Essay Concerning Human Understanding* in the same year. From then on, Locke never ceased publishing: he continually revised and republished his *Essay*, also supervising its translation into French; between 1690 and 1704 he wrote three more letters on toleration (*The Works . . .*, vol. 6, pp. 59–574); in 1690, *Some Thoughts on Education* (*ibid.*, vol. 9, pp. 1–210);

in 1695, *The Reasonableness of Christianity* (*ibid.*, vol. 7, pp. 1–158); various defenses of the *Essay*; economic tracts; and paraphrases of Paul's Epistles. Much of the immediate stimulus to this work was topical: his study of education grew out of private letters to his friend Edward Clarke; the economic tracts all sprang from fiscal and commercial problems of the government; the later writings on toleration were called forth by attacks on his ideas and on William's efforts to solve the problem of dissent in England. Characteristically, however, even his topical writings contain elements of "philosophy," generalizations not required by the work's immediate polemical purpose.

Major contributions

Locke has often seemed a singularly disconnected thinker, an asystematic philosopher with occasional brilliant insights. Since the acquisition by the Bodleian Library of many Locke manuscripts from the Lovelace Collection, the development of Locke's interests and of his thinking can be more accurately traced than before; further, the ways in which his ideas, apparently so disparate, hang together has become clearer from study of the manuscripts. His earliest work was on natural law, which led him ultimately into his serious work on two branches of that large subject, political theory and human understanding. Though these two interests branched widely apart from one another and seemed far removed from his initial concern with the "covering" aspect of natural law, his friends expected, in vain, that he would eventually write a treatise about natural law, after he had completed his *Essay*. His early natural-law essays were written between 1660 and 1664 and deal with both the epistemological problem of knowing in natural law and with the natural law as a binding moral and social force; the essays show clear signs of Locke's later full-scale attack upon innateness and *consensus gentium*, as well as his incipient psychological sensationalism. As for moral natural law, Locke assumed it as a *donnée* from God, binding upon man's reason; this view remains rudimentary both in the *Second Treatise* ([1690a] 1960, pp. 283–446) and in Locke's other writings. In his manuscript treatises on the civil magistrate and on toleration, dating from the early years of the Restoration, Locke moved from a restrictive position to a more tolerant one, at first insisting on public order as a primary value and then stressing the irenic power of the civil magistrate, particularly in the regulation of religious practices. From these early works Locke's philosophical investigations emerged. They will be treated under several headings, with stress laid upon those elements of his

thought most significant for the development of the social sciences: political theory, religious ideas, economic ideas, epistemology, psychology, educational theory.

Political thought. Locke's major contributions to political thought are in his *Second Treatise*, a document notoriously lacking in system, partly because of its remnant character, partly because of its connection with contemporary events, partly because of Locke's failure to rewrite it substantially for publication in 1689, ten years after its completion. Within its own time the work contained "dangerous" doctrines, some anathematized by decree in 1683, when Locke fled his country. By the time of its publication, however, it expressed the parliamentary ideals of mixed government and separation of powers established in England by the political settlement reached after William's invasion. The origins of the tract seem to have been in the Exclusion crisis; it was designed to justify constitutional change, for which Locke undertook to investigate the origins and structure of civil (political) society. His polemical aim was to diminish popular acceptance of the patriarchalism which gave authority to much of the contemporary argument for absolutism; to do so, he postulated an original, direct relation of every man to God rather than to or through any political intermediary. Each man was in some sense God's "property": bypassing the notion of Adam as a model ruler of the social group, Locke postulated a state of nature regulated by laws derived from God, a state of nature in which men were equal and free before the Lord and each other. Paradoxically, the rule of law (in this case, the rule of the law of nature) was requisite for freedom; without such natural law man's "freedom" would have been anarchy. In this sense Locke's conception approached the anarchic state of nature postulated by Hobbes, although his insistence upon fundamental natural law saved him from Hobbes's pessimism about the lawlessness of basic human nature. From this natural condition, Locke inferred both a "law of reason," by which individuals reach and assent to social consensus, and the practical laws requisite to permit, even to insure, personal freedom [see NATURAL LAW]. Originally, in the state of nature, executive power of the natural law was vested in every individual; subsequently—whether suddenly or gradually is not made clear—men consented to live in a common society regulated by the communal executive power of the law of nature. Locke divided this communal power into three—the legislative, executive, and federative powers—with judicial decision a general power of the political commonwealth.

To effect the passage from the state of nature

to "civil society," Locke developed his important variation on the idea of property, which in turn graded into his theory of labor. From the natural-law postulate that a man has property in his own life, Locke derived the view that a man has property in the things necessary to the preservation of that life, so long as those things are rightfully his (that is, taken from the commonwealth at a point when the specific acquisition harmed or deprived no one else). A man has a right in himself and thus in his own labor; in turn, he has a right to what "he hath mixed his labor with," or a right to his property. A corollary of this is Locke's formulation of the labor theory of value, almost incidental to his argument: the value and the price of commodities in any society reflect the labor that has gone into them.

There are two sorts of relations between men, the first a natural social contract, entered into by the exercise of rational considerations of self-preservation, the second defined by rights in property. The function and end of government are the preservation of life, liberty, and property. One corollary of this formulation is that political rights derive from property and that the propertyless are either without political rights or are slaves. Such a conception of the commonwealth permits emphasis both on the common interest and on private holdings, which in Locke's essay (in line with seventeenth-century usage and notions of value) generally means land.

Without in any sense denying the importance and validity of a familial organization of society, Locke demonstrated that the power over children and dependents vested in the father (who shares it with the mother, interestingly enough) is simply a form of trusteeship: the guardian-father has certain obligations toward his children, especially to educate them; when the children reach full exercise of their reason, they are free "from subjection to the will and command of the father." The family was, for Locke, important in his theory of the origins of civil society, the conjunction of male and female being both a symbol of a wider assent and obligation and a primary stage in the voluntary community of mankind. Thus, even in families, arbitrary government is "impossible"; in commonwealths the necessary consent of each individual to enter into the bond of civil society (the social contract) eventuates in election, the choice of representatives charged to exercise legislative power. Legislative power is supreme in Locke's mixed government of separate legislative, executive, and federative powers. His assumption is that a man with political rights (by reason of his property in himself) enters into political life, inheriting with his

property his obligations to the government that represents him. In turn, the government may not touch his property (i.e., levy taxes) without his consent through his representative. One implication of this formulation is a doctrine of resistance, or revolution, as expressed in the last chapter of the *Second Treatise*, the chapter which, above all others, made Locke objectionable to the government before 1688 and valuable to the government thereafter. Unlike the Protestant resistance-theorists of the sixteenth century, Locke did not base his revolutionary theory upon sanctions of conscience or religion; unlike the English parliamentarians of the 1640s, he did not base it on precedents in English law; unlike Algernon Sidney, he did not base it on a metaphysical and metapsychological natural right to liberty; rather, he advocated a restrained and considered revolution for the restoration of proper balance in the body politic. [See SOCIAL CONTRACT.]

Locke's theory of government emphasizes process, both the hypothetical process of human development from a state of nature to civil society and the processes of self-government. He therefore limited the number of specifiable elements in the proper commonwealth and was careful to leave ample room for adjustments to changing social needs. He was, in short, indicating a successful process of representative majority rule rather than setting up an exclusive structure for one. Hence, there are large areas of his thought which seem blank, either because he was unconcerned with total consistency or because he was concerned with leaving social alternatives open, especially in "matters of indifference."

Views on religion. His toleration theory, taken in conjunction with his religious views, demonstrates his appreciation of practical approaches. Thus, his *Letter Concerning Toleration* of 1689, Locke dealt with Christian toleration, "the chief characteristic mark of the true church." Since every man appears orthodox to himself, no one in his right or his wrong mind will accept as just the persecution of himself; furthermore, since in any case persecution cannot touch a man's inmost conviction, regardless of what he may say under stress, there is no practical merit in persecution. Locke politicized the problem of religious pluralism, assigning to the civil magistrate the protection of various rights (here defined as "life, liberty, and indolency of body") of members of a commonwealth. The care of souls was no more committed by God to the civil magistrate than the care of one man's conscience was committed to any other member of society. The magistrate's power consists only in civil force, which is irrelevant to any church (defined as "a voluntary society of men").

From the privileges of toleration, Locke excluded some—he excluded atheists from the benefits of the law, because they refuse to acknowledge its source—but he included idolators, men simply given to erroneous worship. Toleration is to be withheld from religious groups who deny it to others, a view supported by Locke's experiences in France, where persecution of Huguenots reached extremes between 1679 and 1685. Whenever religious assemblies endanger the public peace, then the civil magistrate, on civil grounds, may intervene against them; even then, however, he is not to interfere with their belief, which remains in the category of "things indifferent" and is therefore irrelevant to questions of public order. Although in this work Locke did not justify resistance, rebellion, or revolution for religion's sake, he made it plain that oppression of any kind naturally impels men toward sedition.

In *The Reasonableness of Christianity* Locke defended the Christian revelation against atheism and against natural religion without revelation, demonstrating by scriptural and historical authority the fact of Christ's messiahship. The tract defends the necessity of revelation against the idea of a sufficient natural religion, but at the same time it treats Christ's teachings as the fulfillment and explanation of the moral law of nature. Man's reason cannot by itself discover the full moral law of nature, but it can confirm it. Nowhere in the tract did Locke sanction a particular form of worship, but instead he endorsed a general scriptural Christianity to which, as it were, all Christians could subscribe. (For this, he was roundly attacked as being a deist.) In ways connected with his toleration theory and his epistemology, he adduced the uncertainties of man's perceptions and knowledge to support his minimal articles of faith, drawn from scriptural revelation and corroborated by the action of reason. [See CHRISTIANITY.]

Economic ideas. Locke's economic interests, stimulated during his early association with Shaftesbury, emerged long after in 1691 in *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money* (*The Works* . . . , vol. 5, pp. 1–130) and in 1695 in *Further Considerations* . . . (*ibid.*, vol. 5, pp. 131–206). In these works, he advocated maintaining the interest rate and not devaluing the currency, on grounds of natural law. His economic laws were (1) that the intrinsic value of any piece of goods is not necessarily reflected in its price; (2) that its market value depends upon the proportion of supply and demand (which he called "quantity" and "vent"); (3) that price is determined by the amount

of money relative to the supply and demand for a piece of goods. These laws permit prices to be set with some flexibility, according to varying conditions, and they rely upon a controlling notion in Locke's thought, that of self-regulation toward equilibrium. When it came to practice, as in the cases of the poor and of Irish manufactures, Locke advocated government intervention in economic affairs.

Psychology. The aim of Locke's *Essay* (1690b) was to determine the limits of human knowledge, so that men might address themselves to problems within their power to solve. He set out to describe the process of human understanding, to inquire into probable knowledge, and to determine the nature of ideas. He concluded, very simply, that ideas have two sources, sensation and reflection upon ideas produced by sensation. It turns out, however, in the course of the book, that knowledge can also be intuitional and demonstrative, though in the discussion intuition tends to be assimilated to sensation and demonstration to reflection. Ideas may be either simple or complex: simple ideas are the result of sensation and reflection and are compounded of simple parts which can be found by analysis. Locke attributed reality to the external world and relied upon intuition to explain the relation between an idea and its referent in the external world. Knowledge derived by intuition (such as that of revelation) is "certain"; certain knowledge can also be derived from demonstration but less reliably than from intuition, since errors in reason and in memory may distort the result of demonstration. Locke's ontological proof of God's existence, much like Descartes's, is an example of the fusion of demonstration with intuition: that is, one's own existence is intuited, and from one's own existence God's can be demonstrated. He relied upon the skeptical provisionalism inherent in empirical investigations, both in his recognition of the role probability plays in human understanding and assessment of life and in his recognition of the idiosyncratic formation of each man's personal set of ideas. As in so much of his work, Locke took a middle position in the *Essay*, incorporating elements of skepticism and elements of idealism, combining what we now call behaviorism with gestalt principles. His empiricism embraced both the particular and the consensual: in the ongoing search for true knowledge individual men are required to check their ideas against those of the group, and the group does so against those of any given individual. [See GESTALT THEORY; THINKING.]

Locke's psychological principles are a by-product

of his effort to describe human understanding. His major hypothesis, that the mind is not equipped with innate ideas or principles but is at its formation a "white paper" (his translation of *tabula rasa*), was reached in part through his own empirical observation of children. He concluded that there are only two ways of human understanding, by sensation and by reflection on ideas derived from sensation. His whole notion of "understanding" is developmental; throughout the *Essay* he cited examples from his observation of the successive stages of men's lives. From his observation of children, he demonstrated that their understanding derives from their experience of the external and social world. Approximating modern notions of "control," Locke cited a great deal of evidence from his observation of human beings who were exceptional in that they lacked some "normal" element of apprehension or reflection—children, not yet developed to full powers; idiots; men born blind (including the famous philosophical example of a man who by an operation got his sight); men suffering from amnesia because their heads had been kicked by horses. In spite of their deficiencies, all such people entertained ideas that seemed to them as authentic as those "clear and distinct" ideas that are the hallmark of proper understanding. Madness, drunkenness, and dreaming interested Locke: the Cartesian criterion for human existence, consciousness, seemed to him too narrow to account for the existence of faultily conscious minds. His solution to the problem of identity turned on assumptions now associated with gestalt psychology: on the continuous existence of an organized body whose parts (including its intellectual store) shift over time in relation to one another. So "the night man" and "the day man," the drunken man and the sober man, the madman and the sane man may coexist in the same person, even though their control over consciousness may be intermittent or interrupted. To this notion may be connected Locke's idea of what are nowadays called "roles," the multiple relations, psychological and social (father, brother, son, son-in-law, servant, master, older, younger, etc.), possible and even inevitable in every man's experience. Memory retention, the operation of which was never altogether accounted for in the Lockean philosophy or psychology, plays a major part in maintaining continuous personal identity. One of Locke's major psychological insights, that arbitrary mental connections are "stamped" on men's minds by the chance conjunctions of their experience, appears in the famous chapter on the association of ideas, an afterthought in his organization. There he demonstrated, by a

kind of negative example, the supremacy of experience over rational powers: a man taught to dance in a room containing a trunk could never dance in the absence of a similar trunk; a man nearly axed in a doorway by a berserk village idiot could never go through a door without glancing behind him. So by experience, governing intellectual and emotional constellations are induced in individual minds. This doctrine and that of the *tabula rasa* underlie Locke's precepts for education. [See DEVELOPMENTAL PSYCHOLOGY; LEARNING; ROLE; SENSES.]

In the sense that he postulated ideas as originating in sensation, Locke's psychology is certainly mechanistic. His general concern, however, to establish the same organic interrelationship for the contents of the mind as for the members of the body or the state, tempers his mechanism with organic and developmental notions. Although he conceived of the body as made up of elements in a mechanistic organization, he saw that mechanism as having considerable feedback into its own individual, even idiosyncratic, development. Feedback is in turn not automatic, in his view, since the mind's judgment, the faculty which selects and arranges ideas in relation to one another, is also constantly at work during consciousness.

Locke's social conception of language may serve as a partial model for his ideas of how men understand as well as of how society functions: Although the designation of words is established by consensus, each man may alter it privately for himself alone, according to his individual associations of words and experience. Furthermore, though encountered as datum in each man's life, language is not rigid but is subject to modification over time by the social needs of the group using it.

Pedagogy. Locke's ideas of education follow from his psychology. The child inevitably grows into the man and should grow into as healthy a man as possible. Since each child is strongly individuated, no fixed regime works for all children, but Locke laid down general rules of education, chiefly applicable (as he wrote) to gentry sons whose duty was to undertake public service. Boys were to be educated at home, carefully fed, clothed, and taught to build and preserve good health. The father was to "imprint" obedience on his son but with such care and tact as to turn the child-subject naturally into his friend. Rewards and punishments were to be systematic but moderate (Locke outlawed beating, as making a child slavish). The father, tutor, and governor, charged with educating the child, were to be his moral exemplars; therefore, it was necessary for parents both to regulate them-

selves and to choose their surrogates with care. Though children must learn self-denial, some cravings may be gratified, especially since "craving" is so closely allied to "curiosity," nature's instrument to correct ignorance. So the child must be allowed to learn whenever ready and can often be cozened into learning by means of games and toys. Children's questions must always be answered truthfully, and conversation with them must be free of condescension. Instruction in the nature of reality—including the idea of God, excluding the idea of goblins—was to be undertaken early.

As for learning itself, Locke's program was practical: reading, writing, French, then Latin (for use, chiefly); geography, arithmetic, astronomy, geometry, chronology, history, ethics, civil law, rhetoric and logic, natural philosophy; then Greek and Latin as cultural subjects and, last of all, method. For learning by rote Locke had no use; he also advocated learning such practical subjects as trade and accountancy as well as recreations such as music, dancing, gardening, joinery—all useful to young men of property. Finally, the young man should travel, first at home and later abroad, before settling down to matrimony and his social and political obligations at the age of one and twenty.

Locke's originality and influence

In its day Locke's thought seemed strikingly "new," cast in a new language for any literate man to read; it had, naturally, many sources and analogues in ancient and contemporary thought. His skepticism and empiricism came from deep within the medical tradition; his attitude, and even the words he used, recall Sextus Empiricus and, more often, Montaigne, another essayist concerned with knowing, education, understanding, nescience, and probability. Locke had, too, a recognizably British stoicism, a preference for directness and plainness in morality and rhetoric; he often cited Seneca and the stoical writings of Cicero. His toleration theory derived from a long line of Protestant writers going back to Servetus and Erastus and exemplified by his Arminian friends; there are affinities between his view of church-state relations and the thought of Chillingworth, Falkland, and John Owen. His citations of natural law are to Hooker and Grotius, whose books he certainly knew, though he seems to have referred to them more out of piety and the need for authorities than from any desire to analyze their thought in relation to his own. Although he was a notable revisionist of the Cartesian epistemology and psychology, Locke's doctrine of ideas owes something to Descartes, his psychological theory of sensationalism shares elements of Carte-

sian mechanism, and his ontological proof of God's existence is brief and efficient partly because Descartes's similar proof was so thoroughly argued. Locke's nominalism had many sources: Greek empiricism, the Scotist tradition in scholasticism, and chiefly Francis Bacon and his followers in contemporary England.

However connected to other strands in the history of thought, Locke was characteristically original in pattern and device. His empirically argued rejection of innate ideas and principles, for example, in the first book of the *Essay* ran counter to traditional epistemologies ancient and modern. Among his contemporaries, both Cartesians and Cambridge Platonists, as well as most divines, postulated innateness as the basis of human knowing, relying on both Platonic and Stoical authorities. In psychology and epistemology a major contribution was his concept of the association of ideas, an involuntary experiential formation in the thought of individual men caused by the linkage of their simultaneous experiences. In economic thought his is the first full argument for the labor theory of value; his notions of property, revolution, and the social contract, though deriving from natural-law theory and resistance theory, are combined in a new interrelation and based upon assumptions of the rule of law that are neither narrowly legalistic nor generally metaphysical.

Across the range of Locke's topics of investigation his preoccupations are clear: his constant interest in the relation of thought to behavior, his concern for the balance of individual right and social obligation, his provisional attitudes to solutions, his distrust of dogmatism, his emphasis on equilibrium and self-stabilization. The last emphasis governs his notion of "power," according to which, even though a man is limited in his finite existence by certain conditional restraints, he is nonetheless free to exercise his mind and even his will. Notions of stabilization and equilibrium operate in his epistemology too, where individual understanding is, among other things, conceived as a constant altering of the balance and relationship between different experiences and ideas. Connected with this, one of Locke's personal behavior patterns makes some sense: from the 1650s until the 1690s Locke, wherever he was, joined or organized discussion groups in which ideas could be cooperatively investigated and idiosyncrasies modulated into a permissive consensus.

Locke's influence can hardly be overestimated; nor can it be accurately measured. His idealism, his concentration upon the autonomy of inward life found an extreme, though corrective, disciple in

Berkeley; his skepticism, in Hume. At first his *Essay* was fiercely attacked. Later, except for such idealists as Leibniz and his own pupil, the third earl of Shaftesbury, for most educated people the book seemed to provide as comprehensive a description and explanation of the mind's workings as Newton's of the workings of the cosmos. Locke's influence on deist thought, perceptible in his lifetime and deplored by him, was considerable both in England and in France; his notions of private education were often cited by eighteenth-century English gentlemen at home and in the colonies; his psychological principles were gradually absorbed into accepted belief and can be traced particularly in the work of eighteenth-century novelists (e.g., Richardson, Sterne, and Diderot). Voltaire's enthusiasm for Locke's ideas had considerable effect in popularizing them in prerevolutionary France. As for political thought, the American and French revolutions have been laid at his door: unquestionably his work was widely read in both countries by men concerned for their political rights, but how deeply they read it remains an open question. His epistemology inaugurated a "new way of ideas," his psychology certainly bore fruit in nineteenth- and twentieth-century psychological theory. Locke's works turn up in many auction lists of eighteenth-century private libraries and are found in the libraries of ancient educational institutions in England and America: Trinity College, Dublin, incorporated the doctrines of the *Essay* into its basic curriculum at an early stage, and Locke's influence at colonial Harvard has also been attested.

LOMBROSO, CESARE

Born of Jewish parents in Verona, Cesare Lombroso (1835-1909), the Italian criminologist, was educated by the Jesuits; he received a degree in medicine from the University of Pavia in 1858 and a degree in surgery from the University of Genoa

in 1859. At various times he was an army physician and in charge of the insane at several hospitals, but his major positions, all at the University of Turin, were those of professor of legal medicine and public hygiene, 1876; professor of psychiatry and clinical psychiatry, 1896; and professor of criminal anthropology, 1906. Although he wrote extensively about such diverse subjects as pellagra, the nervous system, and genius, he came into prominence with his major work, *L'uomo delinquente*, first published in 1876. The book went through five editions in Italy and was translated into various European languages, although never into English.

Lombroso was influenced by French positivism, German materialism, and English evolutionism. In particular, he was influenced by Auguste Comte; Charles Darwin; Bénédict Morel, the French alienist who developed a theory of degeneracy; Bartolomeo Panizza, the Pavian comparative anatomist; Carl Rokitanski, the Viennese pathologist; and Enrico Ferri, his principal younger colleague, who suggested to him the term "the born criminal."

Although Lombroso was aware of the importance of social and psychological factors in the causation of crime, his primary emphasis was on the concept of the atavistic criminal. He believed the atavistic criminal to be a biological throwback to an earlier stage of evolution, since inborn delinquency was not natural to contemporary mankind but peculiar to primitive races. The atavistic criminal could be identified by various anatomical, physiological, and psychic stigmata, different kinds of inborn delinquency being identifiable by different patterns of stigmata.

Lombroso later modified his ideas about criminal typology. Because in the first edition of *L'uomo delinquente* he had focused his attention so exclusively on such anatomical and anthropometric data as skull measurements and facial asymmetries, he had been led to an excessive emphasis on one type of criminal and one theory of criminal causation, atavistic criminality. In later editions he expanded his investigations and consequently his theory, adding degeneracy as a cause of criminality and considering atavism to be a form of degeneracy. Although his theoretical linking of atavism and degeneracy was challenged by biologists, it did widen his original narrow concept of the born criminal, which had been the primary point of attack of his critics. Lombroso's investigations also revealed that the born criminal had pathological symptoms in common with the moral imbecile and the epileptic, and this led him to expand his typology to include the insane criminal and the epileptic criminal. The insane criminal type includes the

alcoholic, the mattoid, and the hysterical criminal. Further additions to the typology include the criminaloid—a criminal qualitatively similar to the born criminal but differing quantitatively from him—who had become a criminal more from precipitating external factors than from predisposing internal ones; the pseudocriminal; the habitual criminal; and the person who commits a crime of passion.

Although Lombroso did not believe that all criminal behavior is of organic origin, there is no doubt that he never completely relinquished his belief in the existence of the born criminal type. However, in the fifth and last edition of *L'uomo delinquente* in 1896–1897 reduced his estimate of the proportion of this type to 40 per cent of the total criminal population, and in his introduction to his daughter Gina's summary of his work, *Criminal Man* (1911), he reduced it still further. In response to suggestions by friends and attacks by critics he also came to give more attention to factors in the physical and social environment of the offender. For example, in *Crime: Its Causes and Remedies* (1899) he not only revised the estimate of the born criminal to 33 per cent of the criminal population but also discussed social circumstances which might be partially responsible for encouraging a variety of transmissible biological anomalies that in turn would function within and affect the social structure.

Lombroso was not entirely opposed to the death penalty but believed it should be used only as a last resort. He favored attempts to readjust the criminal and suggested a doctrine of symbiosis of crime, whereby society would make use of the labor and aptitudes of offenders. Included in this doctrine is the idea of the compensation of the victims of crime from the proceeds of work done by prisoners.

Lombroso's work influenced criminological thinking principally by redirecting emphasis from a legalistic concern for crime to a scientific study of the criminal. His approach is most evident in the clinical criminology of Benigno Di Tullio and his associates in Italy.

LONGFIELD, SAMUEL MOUNTIFORT

Samuel Mountifort Longfield (1802–1884), the Irish jurist, had only a brief career as a professional economist; he was the first occupant of the chair of political economy at Trinity College, Dublin, that Richard Whately founded when he was made archbishop of Dublin. Longfield held this professorship from 1832 to 1836 and then resigned to pursue a legal career.

It was in 1903 that Edwin R. A. Seligman (1915) drew attention to Longfield by referring to him as a “neglected” economist, and indeed he appears to have been virtually unread outside Ireland until then. His work certainly deserved belated recognition, even though it had not become part of the mainstream of economic thought, for in some aspects of that work, he was thirty—even sixty—years ahead of his time.

In establishing the determinants of value, Longfield emphasized cost of production as one determinant, and had a rudimentary conception of the importance of diminishing marginal utility of demand as the other determinant. Thus he spoke of price as indicating what the buyer with the least intense demand was willing to pay. The distribution of income, like diminishing marginal utility, was for Longfield a marginal problem—that of productivity. He enunciated a nicely symmetrical theory of factor payments, in the course of which he denied the importance of the cost of subsistence

for the level of wages. He asserted that the wage rate was governed instead by that unit of labor applied least efficiently in the production of any given quantity of a commodity. Nonetheless, like most of his contemporaries, Longfield rejected Malthusian population theory as determining the necessary cost of production of labor, asserting that “. . . to find out what is the cost of production of common labourers, appears to be a trifling with a serious subject” (1834*b*, pp. 202–203).

The cost of capital is the cost of sacrificing present commodities for future ones, and in suggesting the idea of the productivity of roundabout production, Longfield may well, as Seligman points out (1915, p. 113), have sketched a theory of interest that combined time preference and the productivity of capital. But again it was the most disadvantageously used machine—that is to say, the least productive—that determined the rate of interest. In the area of allocation theory Longfield did interesting work in the concept of comparative advantage. This and, even more, the marginalist aspects of his economic analysis may well be connected with the fact that Longfield had always been an able mathematician and in 1872 even published *An Elementary Treatise on Series* (Black 1947, p. 53).

It was consistent with his rejection of Malthus that Longfield did not share the gloom of some of the English classical school concerning economic evolution, and believed that technological improvements in agriculture could more than offset the effects of population increase. He not only advocated that Ireland be industrialized but also predicted that industrialization would over time result in such an increase in capital that the rate of profits would fall and the productivity, hence the real wage, of labor would rise.

Longfield was president of the Statistical and Social Inquiry Society of Ireland from 1863 to 1867, but made few contributions to its proceedings. In a paper to the society (1872*b*), he appears to have supported the idea of government intervention in economic matters, advocating pensions for the blind and the aged, state education, medical care regardless of demonstration of need, housing control, and state-provided clubrooms for workers.

LORIA, ACHILLE

Achille Loria (1857-1943), Italian economic theorist, was born and raised in Mantua and received his *laurea* in law at Bologna in 1877. Subsequently he came under the influence of Luigi Cossa at Pavia, Angelo Messedaglia at Rome, and Adolf Wagner at Berlin. In 1881 he was named professor of political economy at Siena, where he remained for ten years. In 1891 he moved to the University of Padua and in 1903 to the University of Turin, where he taught until his retirement in 1932. He was elected to the Accademia dei Lincei in 1901 and was appointed to the Senate in 1919.

Loria developed his theory from a wide range of predecessors—the English classical school, Marx, Darwin, the German historical school, and Luigi Cossa, a specialist in the history of economic theory. Loria was not, however, a simple eclectic, for he used borrowed ideas to formulate an original deterministic and mechanistic theory of economic

development and social history. From an intensive and extensive reading on landholding in the British Museum in 1882, when land reform in Ireland and England was being very earnestly debated, he came to the conclusion that the key to the historical process is the relationship between the productivity of land and the density of population. Loria contended that the relative scarcity of land leads to the subjugation of some members of society by others. Different forms of subjugation produce stages in the historical process: slavery, feudalism, high capitalism, and late capitalism. Thus, social and political phenomena are determined at each stage by basic economic and demographic circumstances.

This fundamental concept was developed in a large number of books, many of which were translated into foreign languages. In these works an effort was made to substantiate the theoretical statement by presenting empirical evidence, especially that derived from the experience of colonial countries like America. Loria placed great emphasis upon the importance of free land in the history of the United States. Reviews and discussions of his work in the *Political Science Quarterly* of Columbia University introduced his work to many historians and political scientists. Clearly his views had an impact upon Frederick Jackson Turner in the formulation of his theory regarding the role of the frontier in American life and upon Charles A. Beard in his investigations of the place of economic interests in American political behavior (Benson 1950). The wide interest in the works of Turner and Beard has meant that Loria has had a considerable indirect influence on the interpretation of American history.

LOTKA, ALFRED J.

Alfred James Lotka (1880-1949) anticipated many of the ideas of cybernetics and did original work in demography, evolutionary processes, and self-renewing aggregates. Born in Austria of American parentage, he spent his boyhood in France and acquired his advanced education in England, Germany, and the United States. He was employed as a chemist, physicist, mathematician, and biologist until 1924, when he joined the Metropolitan Life Insurance Company. There he worked on tasks that made heavy demands upon his actuarial and demographic skills. Lotka's 95 technical papers and 6 books reflect his deductive acumen, imagination, pragmatism, precision, and erudition. These works,

as well as his magazine articles, also manifest a deep appreciation of the arts and humanities. He held the office of president of the Population Association of America and of the American Statistical Association and several posts in the International Union for the Scientific Study of Population.

His key concern was the set of processes underlying self-renewing aggregates and systems undergoing change, especially irreversible change; this interest prompted the work to which "the field of demography owes virtually its entire central core of analytical development" (Notestein 1950, p. 23). Having shown in 1907 how a closed population with fixed age distribution grows, Lotka (with F. R. Sharpe 1911) demonstrated how a closed population develops a stable age distribution and a characteristic rate of increase, thereby supplying the most powerful of the modern demographer's analytical tools, the stable population model. Building on this and later work, Lotka (with L. I. Dublin 1925) showed how to compute a stable age distribution and the "intrinsic" (or "true") rate of increase, a discovery meriting for him the title "father of demographic analysis" (Vincent 1950, p. 14). This study revealed how misleading crude rates of natural increase can be. Lotka subsequently published many studies of self-renewing aggregates, evolution of age distributions, indices of reproductivity, progeny of population elements, orphanhood, changes in fertility and family size, family extinction, mortality, and so on. Some of this work appeared in the revised editions of Dublin and Lotka's *The Money Value of a Man and Length of Life: A Study of the Life Table*, and a great deal was summarized in Lotka's *Théorie analytique des associations biologiques* (1934-1939).

Probably most representative of Lotka's thought is *Elements of Physical Biology* (1925). Appearing when few social scientists used mathematics, it informed some of them of the uses of differential equations, the mechanics of systems and subsystems and the uses of systemic theory, and an essentially cybernetic view of organismic behavior (Simon 1959, p. 494). The book was the source of certain central modern ideas, and it demonstrates Lotka's ability to discover significance in diverse phenomena. Even today it contributes to the understanding of statics and dynamics. The book focuses upon the mechanics of one of the "systems undergoing irreversible changes in the distribution of matter" among its several components, namely, the evolving "life-bearing system," which is made up of an assembly of biological species, among them man, and collections of certain inorganic materials. Having defined irreversibility and conceived of evo-

lution as the redistribution of matter, Lotka described the fundamental equations of the kinetics of evolving systems, along with growth functions and constraints. Under "statics" he treated steady states and diverse equilibria (e.g., chemical, interspecies, moving); Le Châtelier's principle, displacement of equilibrium, homeostasis, stability conditions, and what is now called "comparative statics"; and the role of parameters which define the state of systems. Under "dynamics" he discussed "the progressive redistribution of the matter of the system" among "aggregations of living organisms" or "energy transformers," together with the inorganic background within which substance circulated and parameters could change, albeit very slowly. He described in detail the elements composing the apparatus which energy transformers use in coping with their external environments, among them depicitors, receptors (including communicators), elaborators, epictors, effectors, adjusters, and "consciousness" involved in depicitors and adjusters [see INFORMATION THEORY]. This nonteleological apparatus enables some organisms, especially man, to discriminate, select, and in some environments stem that increase in entropy which dominates irreversible systems; its influence may be accentuated by favorable orthogenesis.

JOSEPH J. SPENGLER

LOTZE, HERMANN

Rudolf Hermann Lotze (1817-1881), German psychologist and philosopher, was born in Bautzen, Upper Lusatia. His father was a surgeon in the army of Saxony. In the confusion of the Napoleonic Wars, his family moved frequently, finding a permanent home only in 1818 in Zittau. There, in 1828, Lotze entered the excellent classical Gymnasium, graduating cum laude in 1834. In his last years at the Gymnasium, he wrote poetry, as well as a novelistic essay along the lines of Goethe's *Wilhelm Meister*. Strongly influenced by Goethe, and as yet unaware of the works of other thinkers, he began to develop what were to remain the essentials of his philosophy.

Lotze's lack of funds forced him to abandon his literary and other interests and prepare himself for a profession. Following in his father's footsteps, he began, in 1834, to study medicine at the University of Leipzig. He also studied philosophy under Christian H. Weisse, a friend of Fechner's and an adherent of the idealist philosophy of Schelling and Hegel. Lotze's later work was decisively influenced both by his medical and scientific training and by Weisse's idealist teaching.

He completed his study of medicine in 1838 with a dissertation entitled *De futurae biologiae principibus philosophicis*. As a scientist he vigorously opposed the medical mysticism implied in the concept of "vitality," replacing it with mechanistic explanations; as a philosopher, however, he denied that a mechanistic system of explanation is necessarily based on a materialist philosophy. He obtained a master's degree in philosophy at the same time as his medical degree.

Lotze practiced medicine in Zittau for a year, but he soon found the town too confining. Encouraged by his former professor, Weisse, he returned to Leipzig as an instructor in medicine and philosophy; he was appointed associate professor in 1843. While he was at Leipzig he produced the outlines of his scientific life work: the *Metaphysik* (1841), in which he broke with Hegelian idealism; the *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (1842); the *Logik* (1843a); and three articles for Rudolf Wagner's *Handwörterbuch der Physiologie*, "Leben, Lebenskraft" (1843b), "Instinct" (1844), and "Seele und

Seelenleben" (1846). In 1844 he accepted an appointment as full professor at Göttingen, occupying what had been Johann Friedrich Herbart's chair. He remained at Göttingen for 37 years until, at the urging of Eduard Zeller and Helmholtz, he accepted the chair vacated by Harms in Berlin. He died soon after his move to Berlin.

Lotze always remained both a scientist and a philosopher. His works are characterized, first, by his efforts to eliminate mysticism from science by using the causal-mechanistic method and, second, by his concern to dissociate mechanistic systematization from materialist-atheist philosophy. To Lotze intellectual achievement without faith was a *caput mortuum*, and science without causal-mechanistic systematization was not a science. Ultimately, to be sure, what concerned him was the ideal—what *ought* to be—and he saw the understanding of causal relationships simply as a condition for the realization of the ideal. Thus, mechanistic processes are indispensable to the existence of a phenomenon, but they are not its *raison d'être*. In this way Lotze tried to combine mechanistic systematization with ethical freedom, with what he called the dignity of subjectivity. In his own time his postulate of freedom, which went counter to the anti-idealist *Zeitgeist*, was not understood; his contemporaries availed themselves, instead, of the mass of physiological facts he cited—which clearly confirmed the dependence of the psychical on the physical—to support their materialist philosophy.

Lotze's *Allgemeine Physiologie des körperlichen Lebens* appeared in 1851, and his *Medizinische Psychologie: Oder, Physiologie der Seele* in 1852. The latter is the first physiological psychology, the prototype of all later works bearing similar titles. In contrast to Fechner's parallelism, Lotze's psychology is a theory of interaction: sensation is produced by the mind "at the initiative of a neural state." Space is a mode of perception peculiar to the mind. A corollary to this theory of space perception is Lotze's theory of "local signs," which asserts that the world of external space is never simply perceived but rather reproduced by the mind.

His two-volume magnum opus, *Microcosmus* (1856–1864), has two aspects: it is both a polemic against materialist philosophy and an expansion of Lotze's psychology into a comprehensive anthropology. (Its German subtitle is "Versuch einer Anthropologie.") Exploring what he called education (*Bildung*), that is, the conditions under which a human being becomes human, he dealt with such subjects as national temperament, the evolution

of customs and morals, and the influences of home, family, division of labor, and so forth. He regarded the history of mankind as the history of the evolution of the human mind.

Lotze founded no school; he had no disciples. Yet he was a pioneer with some influence, for the friends and pupils he did have were men of scientific importance: Teichmüller, Stumpf, Konrad Langenbeck, and Georg E. Müller. Stumpf studied with Lotze in 1867–1868, and, after working with Franz Brentano in Würzburg for two years, he returned to Göttingen as an instructor. Müller took his doctorate with Lotze in 1873, became an instructor at Göttingen in 1876, and succeeded Lotze as professor there in 1881.

It is unlikely that anyone with an empirical, problem-oriented approach to psychology will find Lotze's work of direct relevance. But if he does not dismiss Lotze's work too readily as obsolete, he may find fertile suggestions there.

WILHELM J. REVERS

LOUIS, P. C. A.

Pierre Charles Alexandre Louis (1787-1872), who did much to introduce the use of statistics into medicine, was born the son of a vineyard proprietor in the small town of Ay (Marne) in Champagne. Although his father died when Louis was six, his mother saw to her son's primary education. After his schooling was over he was sent to a law office to prepare for a legal career. In 1807, deciding that the law was not to his liking, Louis began to study medicine. He spent a year at Reims with a surgeon and then went to Paris to pursue his studies, graduating in 1813 with a medical degree.

A chance encounter during a brief vacation in his native town had an important effect on his career. The comte de Saint-Priest, an emigré noble in whose family Louis's aunt had been a governess, was friendly with the Louis family and paid them a visit. As governor of Podolia, Saint-Priest was in the service of the tsar and persuaded Louis to accompany him to Russia. After traveling about that country for three years Louis settled in Odessa, where he acquired a substantial practice and even received a titular appointment as physician to the tsar. In 1820 Odessa experienced a diphtheria epidemic, an event which led Louis not only to realize

the shortcomings in his knowledge of disease but to give up his practice and return to Paris for further study.

Six months in the Paris hospitals convinced Louis that clinical medicine required a more precise basis than it had and that this could be achieved by what he called the numerical method. A.-F. Chomel, his friend and fellow student, was attending physician at the Charité Hospital and gave Louis the run of two wards of his service, as well as the privilege of performing all the autopsies on the patients who died there. For six years Louis worked at the hospital from three to five hours a day, devoting at least two hours to each autopsy and collecting over two thousand observations. In 1827 he retired to Brussels, where the cost of living was lower, and spent a year tabulating and analyzing his statistical data.

Some of his observations had been published while he was still in Paris, and in 1825 Louis had brought out his *Recherches anatomico-pathologiques sur la phthisie*, based on 123 cases. (Some eighty were added to the second edition of 1843.) By the time he returned to Paris in 1828 he had acquired a reputation in medical circles. That year he was sent, together with Armand Trousseau and Nicolas Chervin, to investigate a yellow fever epidemic at Gibraltar. In 1828 his work on typhoid fever was published and he became attending physician at La Pitié Hospital. Subsequently he was also appointed to the Hôtel-Dieu: he served in these institutions for many years. Louis's last important publication was his critical analysis of the alleged therapeutic effects of bloodletting, *Recherches sur les effets de la saignée dans quelques maladies inflammatoires* (1835). In this book he employed the numerical method to refute the views of François Broussais on copious bloodletting in pneumonia and other inflammatory diseases.

Louis married a daughter of the marquis de Montferrier in 1832, when he was 45. For some twenty years he carried on an ample consultation practice in Paris. His only son, Armand, died of tuberculosis in 1854, a loss from which Louis never recovered.

The numerical method. Louis's major contribution resides in his efforts to apply statistical analysis to problems of clinical medicine. His advocacy and use of the *numerical method* served this end. What Louis did was to study each patient as thoroughly as possible at the bedside and at autopsy, employing rigorously the methodology already established by G. L. Bayle, René Th. H. Laënnec, and others of the Paris school of clinicians and pathologists. Having carefully collected his observations he then grouped them in tabular form. From

these grouped and tabulated data inferences might be drawn concerning the relations between diverse clinical phenomena, the probability of their occurrence, the value of a given therapy, and other items. Although he had used his approach in his earlier publications on phthisis and typhoid fever, the numerical method was first fully presented in 1835 in Louis's therapeutic study, *Recherches sur les effets de la saignée . . .*, and in a special memoir *De l'examen des malades et de la recherche des faits généraux* (1837).

Essentially, Louis's numerical method was not new. The procedure had been employed some three decades earlier by Philippe Pinel to prove the value of his "moral treatment" of mental patients. It was also being employed in the 1820s and 1830s by physicians concerned with such public health problems as the causes of differential mortality and the effect on health of such factors as economic and social class, occupation, race, imprisonment, intemperance, or lack of proper sanitation. Furthermore, Louis's handling of numerical data was basically simple. If, as it is said, Louis was familiar with the work of Laplace on probability, there is no evidence that he ever used such knowledge in his statistical thinking. Like so many of his contemporaries he dealt with small numbers of observations and had no knowledge of how to establish the precision or validity of his results. There is no doubt that Louis was himself conscious of these difficulties; yet he did not seek statistical criteria of reliability, nor did he try to decide when the number of observations was large enough to avoid error.

Nevertheless, Louis has a significant place in the evolving application of statistical analysis to health problems. First of all, he recognized the basic importance of accurate observations. His insistence on good clinical records established a fundamental principle for statistical work in clinical medicine. Second, Louis made an important contribution as a teacher and a propagandist. Through his students, of whom a considerable proportion were foreigners (among them Americans), through the Société Médicale d'Observation (which several of his students founded in 1832), and through his writings Louis advocated and spread the idea of the numerical method, in spite of vigorous opposition. He envisaged the goal of a science of clinical medicine and pointed to the road that would lead to it.

LOWELL, A. LAWRENCE

Abbott Lawrence Lowell (1856-1943), political scientist and president of Harvard University, was born into one of the great families of Boston society. The Lowells had been established in Massachusetts since 1639 and had contributed to American life a distinguished line of ministers, merchants, industrialists, philanthropists, jurists, and poets. Much of their philanthropy supported education, especially Harvard University, the Massachusetts Institute of Technology, and the Lowell Institute. When he graduated from Harvard College in 1877, A. Lawrence Lowell was the sixth in an unbroken series of generations of alumni.

After receiving an LL.B. from the Harvard Law School in 1880, Lowell opened a law office in Boston. When his practice proved unsuccessful, he began to write in his spare time, soon turning from legal topics to political science. A series of magazine articles, collected as *Essays on Government* (1889), received sufficient recognition to encourage him to begin work on a major study in comparative government, the two-volume *Governments and Parties in Continental Europe* (1896). From 1897 to 1900 he was a part-time lecturer at Harvard, and in 1900 he received a permanent appointment as professor of the science of govern-

ment. His book *The Government of England* (1908) won praise on both sides of the Atlantic. Lowell was active in university affairs, and this led to his selection as president of Harvard in 1909, a post he held until 1933.

His basic approach to political science is stated on the opening page of *Essays on Government*: "The real mechanism of a government can be understood only by examining it in action." Studies were needed, therefore, to provide detailed descriptions of the actual operation of contemporary political structures. He observed, furthermore, that political parties, more than formal institutions, determine political practice.

Lowell's two major books were based on these themes. The one on continental Europe (1896) carefully described the formal political institutions of France, Italy, Germany, Austria-Hungary, and Switzerland and the way that the specific party system dominated the institutions of each country. The book on England (1908) provided a detailed review of the political life of that country, based on extensive interviews with political leaders as well as printed source material. These and less ambitious works discussing the management of legislation by parties and the impact of public opinion on party operations aroused contemporary enthusiasm. In the *English Historical Review* it was said that Lowell "has done for England what Mr. Bryce has done for the American Commonwealth" (Raleigh 1908, p. 809). Although succeeding generations may not rate Lowell's insights this highly, they will still find useful his precise portraits of how governments operated at the beginning of the twentieth century.

In his 24 years as president of Harvard, Lowell was particularly eager to enhance the stature of the undergraduate college. He modified the undergraduate curriculum by curtailing freedom in the choice of courses and by introducing the tutorial system to encourage individual work. He altered the structure of the college by the inauguration, in 1930, of the "house system," which split the undergraduate body into smaller residential and social units, on the model of the English universities. And despite his great identification with New England, he supported changes in admission rules and scholarship eligibility that opened Harvard to public school graduates from the entire country and transformed the college into a national institution.

Although Lowell aroused considerable liberal hostility when he supported the convictions of Sacco and Vanzetti, he was keenly sensitive to any encroachments on academic freedom. He strongly defended faculty members under attack by the pub-

lic and by alumni for unpopular opinions—Hugo Münsterberg for pro-German attitudes during World War I, Zechariah Chaffee for liberal views during the "Red Scare" of the 1920s, and Harold Laski for his support of the police in the Boston police strike of 1919.

LOWIE, ROBERT H.

Robert H. Lowie (1883-1957), American anthropologist, was born in Vienna of a German mother and a Hungarian father. From the time he was ten he lived in New York City. In 1897 he entered City College, concentrating on Latin and Greek for the first two years and then on science. After he received his B.A. in 1901 he taught for three years in the New York public schools. Then he began graduate work in anthropology at Columbia University, studying primarily with Franz Boas; his minor field was psychology. He volunteered his services to Clark Wissler at the Ameri-

can Museum of Natural History and was sent by Wissler on his first field trip, to the Lemhi Shoshone, in 1906. In 1908 he received his Ph.D. from Columbia, with a thesis on a subject in comparative mythology. Lowie spent most of his active professional life at two institutions: at the American Museum, from 1907 to 1917, and at the University of California at Berkeley, from 1917 until 1950. He married Luella Cole, a psychologist, in 1933. His last teaching position was at Harvard in the summer of 1955.

Lowie was exceedingly productive: his bibliography totals about four hundred separate pieces of writing—14 books, 18 monographs, 3 translations of monographs, 203 reviews, and numerous articles. Nearly all his works were on ethnology, but he did include some archeology in his *Introduction to Cultural Anthropology* (1934) and collected three volumes of texts in the Crow language. His many honors attest to the recognition of his contributions: he served as president of several major professional societies (the American Folklore Society, 1916–1917, the American Ethnological Society, 1920–1921, and the American Anthropological Association, 1935–1936); he was elected to the National Academy of Sciences in 1931; he received an honorary doctorate from the University of Chicago in 1941; he gave the Huxley lecture at the Royal Anthropological Institute in 1948; and he was awarded the Viking medal in the same year. He also served his profession as editor of the *American Anthropologist* from 1924 to 1933.

Approach to theory. Lowie's theoretical position was, in his own words, middle-of-the-road (*Selected Papers*, p. 13); for example, on the subject of the correlation of semantic categories in kinship terminologies, on the one hand, and social structure and behavior, on the other, he took a position somewhere in between Kroeber's historical one and the functional view propounded by Radcliffe-Brown. He refused to accept theories when he considered the supporting evidence to be weak, as in the case of Freudian interpretations of cultural behavior, for he insisted that ethnology is a science and that its theories must be supported by facts.

Of all Lowie's books, *Primitive Society* (1920) had the greatest impact on anthropology. Although Kroeber criticized the book for being too destructive of old theories and too little concerned with replacing them (Kroeber 1920), and although White repeatedly berated Lowie for being too harsh with L. H. Morgan (White 1943; 1944; 1945), *Primitive Society* dominated social organization theory until the almost simultaneous ap-

pearance of three new books, one by Lowie himself (1948), one by Murdock that appeared in 1949, and one by Lévi-Strauss, also in 1949. Lowie's 1920 book would have been great even if it had done nothing more than clarify terminology, but it contained so much more that graduate students reading it for the first time are often surprised to find that it anticipates much of current teaching.

Although Lowie used no explicit sampling technique, he was familiar with so wide a range of ethnographies that many of his global generalizations have since been confirmed by more refined methods. The broad scope of the book, which includes chapters on property, associations, rank, government, and justice, in addition to the discussion of kinship, is paralleled most closely by Hoebel's general textbook, published in 1949. Lowie's theoretical position in *Primitive Society* reflects that of the Boas historical school. While not denying independent invention and parallel and convergent evolution, especially in the field of economics, Lowie did reject the evolution of social organization proposed by L. H. Morgan and emphasized the dominant role of diffusion: "Creating nothing, this factor [diffusion], nevertheless makes all other agencies taper almost into nothingness beside it in its effect on the total growth of human civilization" ([1920] 1947, p. 434).

Lowie's *History of Ethnological Theory* (1937) shows more tolerance of the opinions of others than does *Primitive Society*. Although Lowie regarded many of the extreme diffusionist views and evolutionary sequences of the German *Kulturkreis* school as being undemonstrable, he nevertheless conceded (1937, p. 190) that the correlations the German anthropologists had obtained between feminine tillage, matrilineal residence, matrilineal descent, bride service, and monogamy were correct. These correlations have been confirmed statistically in recent years. Similarly, although Lowie had little use for Radcliffe-Brown's more general laws, he accepted the correlations Radcliffe-Brown had established among specific variables of kinship terminology and social organization. For instance, Radcliffe-Brown (1913) was the first to point out that in Australia four-section systems of social organization and marriage with a first cross-cousin were associated with one kind of kinship terminology, while eight-section systems and marriage with a second cross-cousin went with a different kind of kinship terminology.

Psychology and anthropology. Lowie maintained an interest in psychology throughout his life, mentioned it in many of his writings, and devoted a section of his *History of Ethnological*

Theory (1937, pp. 262–274) to it. He regarded psychology as the study of innate behavior, in contrast to the learned behavior of culture, and he pointed out that ethnological studies had shown that many kinds of behavior are in fact culturally determined, although they had previously been thought to be of genetic origin. At the same time he suggested that mythology and religion have common elements across cultures which are derived from dreams, and that these dreams may have some sort of biological basis. Lowie accepted Galton's notion that individual differences between members of the same society may be in part genetically determined, and even that there might be significant genetic differences between races, not in over-all ability but in special abilities, such as aptitude for music. He was among the first anthropologists to point out that cultural selection is a part of natural selection (1937, p. 267) and that it can in part determine which genes will be advantageous and which will be deleterious. He tended to distrust the sweeping Freudian generalizations of the early personality studies by ethnologists and never fully endorsed personality as an important subdiscipline within ethnology.

During World War II, Lowie taught an "area course" on Germany and the Balkans at Berkeley. This led to a book on Germany (1945), a field trip to Germany, Switzerland, and Austria in 1950/1951, and a second book on Germany in 1954. Lowie did a considerable amount of interviewing on the field trip, and he read a large amount of material on Germany, including self-evaluations by Germans. The 1954 book was concerned principally with describing the impact of the war on the personalities of German people.

Anthropological analysis. Lowie's many monographs on North American Indians, which were written for the most part while he was connected with the American Museum, are excellent. His field work on the Crow Indians goes far beyond the kind of cultural inventory that was common at the time and includes many insights into functional relationships. Take his description of the chaos that would result from an endogamous marriage within a single sib (or clan):

A Crow in such circumstances loses his bearings and perplexes his tribesmen. For he owes specific obligations to his father's relatives and others to his mother's, who are now hopelessly confounded. The sons of his father's clansmen ought to be his censors, whereas his mother's are bound to shield him from criticism; but now the very same persons are his joking-relatives and his clansmen. The dilemma affects others as well as himself. ([1948] 1960, p. 237)

The historical and comparative summaries at the end of his work on Plains Indian age-societies (1916a) were praised even by Boas, who was critical of so many historical reconstructions. They are still cited as among the best examples of the kind of comparative and historical interpretation produced by the Boas school.

It was in one of his early articles (1916b) that Lowie showed how well a balance can be preserved between historical and "sociological" (i.e. functional) interpretation of such data as kinship terminologies. Indeed, since more recent cross-cultural studies of kinship terminologies have largely ignored historical explanations, they have in this respect retrogressed from Lowie's position of 1916. However, in works by Naroll (1961; 1964), Naroll and D'Andrade (1963), and Driver (1966), Lowie's dual interpretation has been confirmed in applications to geographical distributions. It is an interpretation that can, in fact, be applied to almost all anthropological data.

Lowie wrote a number of articles in which he drew on more than one academic discipline (see *Selected Papers*, pp. 189–290) and in which he reached, among others, the following conclusions: that oral traditions are not reliable history and that a more accurate history can be inferred from careful comparative study in ethnology, archeology, linguistics, and physical anthropology; that all races are not necessarily equal in all inherited mental abilities just because they have not been proven to differ; that the concept of incorporeal property is common in primitive societies; that economic factors can explain only a minor part of cultural behavior; and that the progression from American Indian societies with the simplest form of government to the totalitarian state of the Inca was not a simple one. There was no unilineal development toward ever greater centralization of authority; for example, the Iroquois avoided military despotism because it would have conflicted with the separatism of their matricentered kinship organization.

Lowie's theory of evolution acknowledged the general increase in culture complexity through time and the increase in the efficiency of economic productivity, but it denied the inevitability of any universal increase in complexity and efficiency: particular races, languages, or cultures may either level off, retrogress, or become extinct rather than evolve toward greater complexity. Lowie also denied the inevitability of moral progress.

Lowie was early aware of the possibility and desirability of applying correlation techniques to cross-cultural variables, and in a book published

in 1948 he also discussed the relation of correlation to the laws of evolution. Although he himself never applied the method of correlation to cross-cultural data, he praised Murdock's 1949 book for doing so. He was well aware of the essentials of scientific method in cross-cultural comparisons, such as the necessity of basing generalizations on representative samples. He pointed out also the lack of precise definition of the ethnic unit (society) and the equally vague definition of some of the variables (culture traits) being correlated. Rather than abandon quantitative methods entirely, Lowie argued for refinement of such definitions and caution in inferring time sequence or causality from correlations. In his books of world-wide scope he consistently cited sufficient evidence from every major world area, so that the generalizations he made have never been invalidated by statistics or even been challenged. In his comparative writings he made use of all the major explanations of resemblances in the culture inventories of ethnic units: universals, parallels, convergences, diffusions, and heritages from a common protoculture.

Most of Lowie's field work was done under the supervision of Clark Wissler of the American Museum of Natural History, who directed him to do reconnaissance in central Canada and the entire Great Basin area in the United States. When he was permitted to remain with the Crow Indians for a relatively long period of time, Lowie's field work was superb. His modest appraisal that his descriptions of material culture were not as competent as Wissler's may be correct, but his work on social organization and religion surely excelled that of his mentor and became a model for those who followed. He obtained most of his information from a small number of informants, but he occasionally used a larger number when he suspected significant individual differences, as in reports of visionary experiences. In addition to collecting material in English from competent bilinguals, he obtained three volumes of texts in the Crow language, thus preserving for the future a large amount of primary data.

LOYALTY

Loyalty can be defined as a feeling of attachment to something outside of the self, such as a group, an institution, a cause, or an ideal. The sentiment carries with it a willingness to support and act in behalf of the objects of one's loyalty and to persist in that support over an extended period of time and under conditions which exact a degree of moral, emotional, or material sacrifice from the individual. Josiah Royce captured most of the connotations of the term when he defined it as "the willing and practical and thorough going devotion of a person to a cause" (1908, pp. 16-17).

As used in political discourse, the concept of loyalty occupies the ground between patriotism and obligation. It is something less than the typically uncritical adulation of one's own political group, often accompanied by rejective attitudes toward outsiders, which is the heart of patriotism. It is something more than the formal, rationally justified duty to obey law, which is the essence of obligation. Loyalty is cooler in emotional tone, more rational in its bases, and less comprehensive in its object than patriotism; and it is warmer, less rational, and more comprehensive than obligation.

Since loyalty is an attitude, it varies along the same dimensions as any other attitude: intensity, specificity, endurance, direction, content, and so forth. Loyalties emerge out of a social matrix, and the processes of loyalty formation, growth, and change are closely akin to those involved in the process of identification. When one is said to be loyal to a group, for example, it is tantamount to saying that he has identified himself with the group, that his membership in the group forms part of his own self-definition, and that he perceives his own interests and purposes as integrally connected with those of the group. Loyalty thus has both instrumental and affective components.

Political loyalties are those directed toward political objects that are of importance in the life of the political community. These objects include formal institutions, parties, interest groups, political leaders, social and economic classes, military organizations, constitutions, traditions, and symbols and myths which a population perceives as embodying or representing the community, history, and destiny which make them a distinct people. Political loyalties form part of a system's political culture—that particular constellation of normative, practical, and emotional orientations toward political things shared by the population of a political system (Almond & Verba 1963, chapter 1). Loyalties can be directed toward a variety of objects

within the political system, and systems can easily and usefully be classified according to the strength, incidence, objects, and patterns of loyalties among the citizenry. [See *POLITICAL CULTURE*.]

Patterns of loyalty. Since loyalties sustain both the individual and the polity by laying the groundwork necessary for shared effort and unity of purpose, loyalty is a very old subject of political discourse, and virtually "all serious political writing regards the quality of loyalty as a good thing" (H. B. White, quoted in Grodzins 1956, p. 16). Classical Greek and Roman writers regarded loyalty as the supreme political virtue, and while few persons in the ancient states enjoyed the status of citizenship, those who did were taught to regard the role of citizen as the noblest of all roles. Duty to the state was the highest duty, and loyalty was the highest value. This evaluation of political loyalty and citizenship permeates the writings of Plato, Aristotle, Thucydides, and Plutarch. Early Christian writers, however, placed little value on loyalty to city or state; for them, religious salvation was the supreme goal, and loyalty to the church and creed that held the keys to that kingdom the highest loyalty. Between the fall of the Roman Empire and the rise of the nation-state, political loyalty, except in the form of the local and semi-personal loyalties of feudalism, mattered little to individuals. Machiavelli's reassertion of the primacy of political loyalty—his statement that he preferred his country to the safety of his soul—was considered blasphemous in the opinion of his time. The modern idea of mass political loyalty and the conception of the nation as the capstone and most comprehensive object of loyalty are really no older than the eighteenth century. They appeared with the French Revolution and reached their most passionate expression in Rousseau's plea for a "civil religion" (*Social Contract*, especially book 4, chapter 8).

Patterns of thought and behavior involving loyalty have been complex and contradictory since the end of the eighteenth century. On the one hand, a number of liberal internationalist thinkers have attacked loyalty to the nation-state as an outmoded and dangerous conception. They argue that increasing national interdependence requires a shift of loyalty away from the nation-state to the institutions and symbols of the international community. On the other hand, the totalitarian states of the twentieth century have demanded of their subjects a degree of concentrated loyalty toward national political leaders, institutions, and policies which is without precedent. Also, the creation of many new states in the underdeveloped areas of

the world has meant a renewed growth of national loyalties at a time when such loyalties may be on the wane in the highly developed states.

It is characteristic of the advanced, complex, highly industrialized states that the loyalties of individuals tend to be numerous, segmental, and increasingly instrumental. The individual yields partial loyalty to many objects instead of giving all his devotion and allegiance to one or a very few objects. Similarly, peer-group loyalties increasingly supplant hierarchical affiliations. This is part of the meaning of the movement from "status to contract" [see the biography of MAINE] or from *Gemeinschaft* to *Gesellschaft* [see the biography of TÖNNIES]. One strand of modern social criticism laments this transformation in loyalty patterns as the "decline of community," while another welcomes it as the advent of an era of increased individual liberty.

Over and above these matters stands the dominant fact that no political system can long endure or enjoy much stability unless its citizens, and especially the elites, place a high value on political loyalty. Among the emerging nations, the development of sentiments of national loyalty and identification is a task of the highest priority (Pye 1962). Many of the emerging nations are riddled by tribal, ethnic, linguistic, and regional divisions. The inhabitants must be urged to abandon their parochial loyalties, and they must be imbued with a sense of affiliation with the national community and a willingness to obey the directives of central authority. Links must be forged in the minds of individuals between their personal interests and joys and the policies and institutions of the state. In order to do this, governments employ all the resources of propaganda and communication to reach the masses. Promoting nationalist ideologies, publicizing the activities and words of charismatic leaders, fomenting antagonism toward foreign governments and peoples, and developing programs of mass action and ritual participation are among the standard methods used in these attempts to build national loyalties. [See MODERNIZATION.]

In a political system that has existed longer as an entity and reached a higher stage of political and economic development, the problem is not to create national loyalties but to maintain them. There, loyalty is both a product of the individual's direct identification with and involvement in the nation's history, symbols, institutions, and destiny and, indirectly, a product of the individual's private satisfactions. Rewards and satisfactions gained in the private sphere have a kind of spillover effect,

and political objects receive the benefits of the individual's gratitude for the joys of personal life. In addition, the level of communication and integration is higher in such states, and inhabitants are frequently exposed to political symbols and messages. The public schools carry the message of patriotism and loyalty to millions of children: after an extensive review of European and American experience, Merriam (1931) concluded that the public school had become the dominant agency for transmitting the themes of loyalty and "civil religion," having largely replaced the army, the church, the family, and patriotic rhetoric in performing this function. In such polities, through the processes of political socialization, attitudes of loyalty toward the nation are widely shared. The national political community forms a common reference point for nearly all citizens. [See SOCIALIZATION, article on POLITICAL SOCIALIZATION.]

Thus, loyalty is the ordinary condition. Although political loyalties are not prominent for most people most of the time, they are there in the background and can be evoked by the appropriate stimuli. Since loyalty is the ordinary condition—the atmospheric condition—active disloyalty is very difficult: custom, the climate of opinion, informal and formal sanctions, inertia, fear, the lack of clear alternative objects of loyalty—all these forces work to assure that even those who are not actively and intensely loyal are at least not *disloyal*. Ordinarily, political authorities do not ask for more than that, for it is enough.

Multiple loyalties. Few persons are loyal to just one object. Most men move within a network of loyalties—to primary group, party, occupational group, clubs, and so forth. In the liberal-democratic states, these partial loyalties are not regarded as incompatible with a larger, comprehensive loyalty to the political community. In fact, these circles of particular loyalties are held to be the very foundation for firm loyalty to the nation (Grodzins 1956). This view, which is widely held among modern pluralistic theorists, is really a rediscovery of Burke's insistence that what holds society together and gives it meaning and richness is the multiplicity of its "little platoons," its primary associations of individuals. Individuals, then, are tied to the central symbols and agencies of the political system through a series of linkages formed by loyalties to smaller groups [see IDENTIFICATION, POLITICAL].

In an important study, Shils and Janowitz (1948) found that while goals and policies might be set by central political authorities, individuals

acted in accordance with those policies not so much out of direct loyalty to the nation as in response to the smaller, primary groups in which they were involved. This was found to be the case within the German army during the Nazi period. The finding thus runs counter to the whole totalitarian conception of loyalty, which insists that all loyalty must be concentrated directly around one political center. As Mussolini stated the totalitarian conception of loyalty, "Fascism takes a man from his family at six, and gives him back to it at sixty." Contrary to this conception, it seems clear that lesser loyalties must exist even in totalitarian states and that these lesser loyalties constitute the individual's primary attachments. It is through them that he is tied to the state, and it is largely in response to them that he loyally accepts and executes his duties to the state.

The existence of multiple loyalties implies the constant possibility of conflicting loyalties. Hence, conflict of loyalties is a theme that entered political writing along with the subject of loyalty itself, and it is already present in the story of Abraham and Isaac and in the tragedy of Antigone. Conflicts of loyalty are especially important during times of rapid social change and when the state feels threatened from within and without. During such times, individuals are uncertain of the intentions and the reliability of others, and the old patterns of belief and affiliation conflict with the new patterns that are emerging. Governments are then likely to require formal professions of loyalty, to undertake investigations of loyalty, and to insist on public adherence to official ideology (see Brown 1958; Schaar 1957). Loyalty is equated with conformity, criticism with disloyalty. The concept of "loyal opposition," one of the supreme achievements of the liberal-democratic regimes, is placed in jeopardy.

Still, while conflicts of loyalty are dramatic and painful, it must be repeated that loyalty is the normal condition. Individuals, by processes similar to those subsumed under the theory of cognitive dissonance, tend to perceive their loyalties as mutually consistent, even when they might appear inconsistent to an observer. Or they tend to rationalize incompatible loyalty imperatives as not really incompatible after all.

In most political systems there is a measure of ambiguity as to just what one must be loyal to in order to be regarded as loyal. Does one owe loyalty to the nation? The government? Traditions and ideals? A mission? Rulers? Hence, actions which seem to be disloyal by one standard may be justified as entirely loyal by another. In all these ways, individuals are able to "save the appearances," to

regard themselves as loyal and to defend themselves against charges of disloyalty.

Political loyalty is supremely important both for individuals and for political communities, and many psychological mechanisms and social processes work to build and maintain it and to assure that loyalty rather than disloyalty or conflicts of loyalty will be the rule.

LUBBOCK, JOHN

Sir John Lubbock (1834-1913) was an English biologist, anthropologist, and popular writer on science. His father, Sir John William Lubbock, was for forty years a distinguished member of the English scientific community and at the same time the successful head of the family banking establishment. The son achieved a similar kind of dual identity, adding to his scientific achievements a successful career in government.

Lubbock was essentially self-taught, although he did receive a certain amount of classical education. After entering the family banking business at the age of 14, he began to study natural history, following a program he had prepared himself. In the mid-nineteenth century the renaissance of natural history was an important event on the English intellectual scene; as a participant in this renaissance Lubbock was one of the first to investigate the social behavior of animals, and he published important studies in zoology and botany.

Apart from the mathematical and scientific interests of his father, the most compelling influence on Lubbock's development as a scientist was the relationship he established, while still an adolescent, with Charles Darwin. Darwin was then already a distinguished naturalist; he was also a friend of the elder Lubbock and his neighbor at Down. Darwin left no students and only a few protégés, of whom Lubbock was the first. Lubbock became an ardent supporter of Darwin's evolutionism when the *Origin of Species* was published in 1859. He was the youngest of that small articulate band whose reasoned and informed defense of the new doctrine led to its general acceptance within a decade; and all of his subsequent work was infused with the excitement of applying the theory of evolution.

Basic to all of his work was the underlying point of view that a science of human society is both necessary and possible: like other phenomena in nature, human society may be subjected to objec-

tive description leading to the formulation of general principles.

The discovery of man's great antiquity and the almost simultaneous publication of the principles of organic evolution by Darwin, in 1859, provided the essential theoretical elements for all of Lubbock's subsequent work in anthropology. Drawing upon an increasing body of data concerning the variation in human behavior, he constructed an over-all theory of cultural evolution that came to be the mainstay as well as the hallmark of English anthropology for almost half a century, even though his extreme position was rejected by more objective scholars. In *The Origin of Civilization and the Primitive Condition of Man* (1870) he developed a theory of the evolution of man and culture that rested on his equation of primeval man and the contemporary primitives. His extreme emphasis on the ideas of "natural progress" led him to arrange his materials (social, ethical, and technological) along a slowly ascending line leading to modern (nineteenth-century) perfection.

Lubbock's deserved reputation as a popularizer of developments in biology and anthropology, and the occasional innocence with which he approached fundamental problems in these fields, should not be permitted to conceal the significance of his own original contributions to both fields, especially to the nascent field of anthropology. He was the first to compile and synthesize the scattered data concerning the prehistory of Europe and North America, in a series of articles that formed the basis of his *Prehistoric Times* of 1865. But he believed that archeology is more than description and that it forms the link between geology and history. He clearly defined prehistoric archeology as a concern of anthropology and saw the reconstruction of past cultures as part of the evolutionary history of the continuous past rather than as the simple collection of monuments and antiquities. Prehistory was established as a science of man rather than an adjunct of classics or art history.

Lubbock drew upon ethnographic descriptions of contemporary "savages" to discover the use and cultural context of archeological materials. In reclassifying the stone tool categories formulated by Danish archeologists he coined the term "paleolithic" to designate the chipped tools found in caves and glacial gravels. He further suggested that these tools preceded a stage of development that he called "neolithic," characterized by the polished stone implements found in Danish peat bogs. Lubbock never accepted the revision of this scheme that was proposed by Mortillet.

On a practical level Lubbock used his parlia-

mentary position and his private means to instigate the passage of the Ancient Monuments Act in order to protect the ancient monuments of Britain against destruction.

LUKÁCS, GYÖRGY

György Lukács, literary critic and Marxist social theorist, was born in 1885 of wealthy Jewish parents in Budapest, then the second capital of the Austro-Hungarian monarchy. His father was a director of the Budapest Kreditanstalt, the leading bank in Hungary. A member of a remarkable generation of Hungarian Jewish intellectuals, many of whom later emigrated to Western countries and made their mark in the sciences and the humanities, Lukács received a cosmopolitan education. From adolescence he displayed a lively interest in European literature and a talent for literary criticism. His earliest critical writings date back to 1903 (when he was 18), and a two-volume study of the modern drama, written in Hungarian in 1908-1909, was published in 1911. In the same year Lukács issued the first German-language edition of any of his works, *Die Seele und die Formen*, which had been published in Hungarian in 1910, and from this time onward he partly abandoned his native Hungarian in favor of German as a medium of public and private discourse. (He came to be known widely by the German form of his name, Georg Lukacs.)

Early intellectual experience. A complex intellectual development carried Lukács from early involvement with the aestheticism fashionable be-

fore 1914 to a prominent role in the German and east European communist movements after 1918. Prior to the outbreak of World War I, he shared with other central European intellectuals of his generation a pronounced distaste for politics and a commitment to the autonomy of art, not merely as an aesthetic principle but as a way of life. This attitude implied a criticism of bourgeois society, albeit its criteria were derived from Nietzsche and the aestheticism of the 1890s rather than from Marx. Like Thomas Mann, for whom, even in later years, he retained an admiration which Mann to some degree reciprocated, the youthful Lukács considered bourgeois society inherently hostile to the arts and specifically to the aesthetic claim to possession of certain intuitively apprehended truths about the nature of reality.

After early studies in Budapest, Lukács moved to Berlin and later to Heidelberg, where he stayed until 1916. During these prerevolutionary years he studied social science and philosophy, and in particular came under the influence of Max Weber and Georg Simmel, who introduced him to sociology. He was likewise influenced by the philosopher Emil Lask, who had constructed a logical bridge leading from the then dominant Neo-Kantianism to the phenomenological school founded by Edmund Husserl. At the same time, Lukács became acquainted with the literary critic Friedrich Gundolf, a member of the esoteric circle around the poet Stefan George, in which both the Nietzschean contempt for democracy and the aestheticist cult of the individual sensibility had been pushed to their farthest limits. The residual influences of this period were to plague Lukács in later years, when (after first going through a Hegelian phase) he had become a more or less orthodox Marxist.

Lukács's own account of this transformation, while not wholly trustworthy, lends due emphasis to the impact of the 1914-1918 war upon the generation of central European intellectuals to which he belonged and whose concerns he shared. In the preface (dated July 1962) to the new edition of his *Theorie des Romans* (an essay on the novel, drafted in 1914-1915, first published in a literary journal in 1916 and, expanded, in book form in 1920), he describes his wartime mood as one of despair, from which he was eventually rescued by the events of 1917—that is, by the Russian Revolution. Prior to this he had been tormented by the—as it seemed to him—depressing choice between the prospect of a German victory and the triumph of “Western civilization,” which as a youthful Nietzschean he had learned to identify with soulless commercialism and materialism. This was also

how the issue presented itself to conservative German intellectuals like Thomas Mann (see the latter's *Unpolitical Reflections*), but Mann gradually and hesitantly accepted Western democracy as the lesser evil, if not as a positive good, while Lukács opted for Lenin.

Heterodox Marxism. Lukács's return to Budapest and his subsequent involvement in the Hungarian revolution of 1918–1919 coincided with a major change in his philosophical and political orientation: his acceptance first of Hegelianism and later of Marxism. Philosophically, the way for this conversion had been paved by his earlier rejection of Neo-Kantian epistemology insofar as it applied to the aesthetic realm, where, it appeared to him, intuitive apprehension of absolute truth is possible. Even as a youthful Neo-Kantian around 1910, he had not quite accepted the doctrine that knowledge of the empirical world does not extend to the nature of ultimate reality but is confined to phenomenal appearances, which in the last resort are the product of human understanding. He was not satisfied with this positivist interpretation of Kant, which Weber accepted, and for a while found solace in the belief that—in the arts at least—ultimate reality is cognizable through intuition of “pure essences.” From about 1916 onward he came to believe that Hegel offered a way out of the impasse created by positivist science. The solution seemed to lie in treating the moral and aesthetic values (deemed by Weber and others to be wholly subjective) as entities located in the structure of reality and as such cognizable by philosophy, although not by empirical science. To this fundamental belief Lukács has adhered, with the necessary consequence that his Hegelianized Marxism has always appeared heretical to the adherents of Soviet orthodoxy, although not to Marxists faithful to the tradition of German idealism.

After brief involvement, as commissar for education, in the short-lived Hungarian communist regime of 1919, Lukács moved to Vienna, where as editor of the official party journal, *Kommunismus*, he came into conflict with the dominant faction. A dispute within the Hungarian Communist party over political tactics culminated in 1923 in the publication by Lukács of a collection of essays best known under the original, German title, *Geschichte und Klassenbewusstsein*. The appearance of this work initiated his new career as a semiheretical exponent of Marxism–Leninism, while at the same time it effectively ended his position as an official party spokesman. In later years he was to be an influential figure in the intellectual life of the Hungarian Communist party, but he never again held

an official party position, and his utterances on literary and philosophical topics were henceforth regarded with suspicion by those Hungarian communist theoreticians (some of them his former pupils) who in 1923–1924 had committed themselves to the official Soviet interpretation of Marxism–Leninism.

Without going into the details of this controversy (a succinct account of which may be found in Watnick 1962) it can be said that Lukács's general orientation clashed with Lenin's pre-Hegelian (indeed, pre-Kantian) understanding of philosophy, while at the same time he pushed Lenin's implicitly elitist view of the Communist party's role to the point of paradox. In recovering the Hegelian dimension of Marx's own thought, Lukács had unwittingly transgressed upon Lenin's version of Engels' “dialectical materialism,” with its naively pictorial interpretation of the role of consciousness. Philosophically speaking, he appeared to his Leninist critics as a left-wing Hegelian rather than a materialist. At the same time he allotted to the role of revolutionary “consciousness” an importance quite consonant with Lenin's own conception of the “vanguard.” The consequences of this contradictory commitment were to pursue Lukács for years, down to the abortive Hungarian rebellion of 1956, which resulted in his temporary banishment and forced withdrawal from public life.

Acceptance of orthodoxy. From 1933 to 1945 Lukács, like most other leading Hungarian communists, lived in Moscow, where he somehow escaped the great purge of 1936–1938. Those Hungarian communists who had sided against him in 1923–1924 (principally József Révai and László Rudas) had meanwhile become orthodox Stalinists, while Lukács himself—although from about 1932 the most doctrinaire of Leninists—paid only lip service to Stalin's “theoretical” contributions. He did, however, purge himself of his idealist errors by solemnly denouncing (in an address to the philosophical section of the Communist Academy in 1934) his 1923 work *Geschichte und Klassenbewusstsein* as an unwitting departure from Marxist–Leninist orthodoxy. After recalling the early influence upon him of Simmel and Max Weber, he named Georges Sorel as one of the pre-1914 writers who had reinforced his leanings toward what in 1934 he termed “romantic anticapitalism.” Having stigmatized his earlier views as “objectively” counterrevolutionary, he paid a special tribute to the significance of Lenin's philosophical work, *Materialism and Empiriocriticism*.

This self-abasement set the tone for the literary productions of the following two decades, culminat-

ing in *Die Zerstörung der Vernunft* (1953a), a bulky 700-page diatribe against modern philosophy, couched in propagandist, indeed abusive, language. Its central thesis—the ideological decay of “bourgeois irrationalism,” from Schelling via Nietzsche to the philosophers of the Third Reich—was worked out at such a primitive level that even some of his sympathizers in the West began to despair of Lukács.

Sociology of knowledge. An assessment of Lukács's significance as a forerunner of what is currently known as the sociology of knowledge must proceed from the recognition that as a theorist he has been primarily concerned with other than sociological topics. The “class consciousness” which appears in the title of his 1923 collection of essays (his only sustained excursion into sociopolitical theory) is not the empirical consciousness of the actual working class, but a political consciousness “imputed” to it (*zugerechnet*, to use his term) on extraempirical grounds. Lukács thus is not a sociologist, not even a Marxist sociologist. He took over from Marx the notion of social development through class conflict, culminating in a new type of society without classes, but did not attempt to apply it to the new postbourgeois reality around him. In particular he remained indifferent to the problem of social stratification in industrial society, as distinct from the issue of class relations in bourgeois society. As a critic of bourgeois culture he was content to rely on the Marxist analysis of capitalism. This furnished him with the assurance that industrialism could provide the economic basis for an organization of social life in which human labor would recover the dignity it had lost, and that human “alienation” (a term not explicitly employed by him in 1923, but inherent in his critique of “objectification”) would be overcome.

Culture. The area where Lukács nonetheless has come to grips with genuinely sociological issues is that of culture. According to the Marxist hypothesis, a class with a genuine historical role is, among other things, the bearer of a new world view and ultimately of a new civilization. Lukács has tried to employ this concept in his voluminous writings on aesthetics. Basing his work on the principle that a particular outlook (variously described as “materialist” or “realist”) has been shared by the bourgeoisie in its early revolutionary phase and the working class in its subsequent effort to build a higher culture, he has tried to safeguard the heritage of classical bourgeois realism. The antithesis of this classical realism is manifest, according to Lukács, in the various forms of modernism, which (in common with Soviet orthodoxy, although

in more sophisticated terms) he has denounced as “decadent.”

Ideology. The ascription to the labor movement (and in particular to the Communist party as the supposed “vanguard” of this movement) of a viewpoint radically different from that of the collapsing bourgeois society furnished Lukács with a criterion for his definition of ideology. He attributed “false consciousness” (ideology) uniquely to the self-definition of the ruling class, while crediting the submerged revolutionary class with the possession of a “true consciousness,” albeit imperfectly articulated and thus necessitating the separate existence of a “vanguard” of theorists in the shape of the Communist party. In principle the working class is held by Lukács to possess a theoretical insight into the historical situation superior to that of the bourgeoisie, although in the actual waging of political conflict this insight needs to be supplemented by the intellectual efforts of the Marxist party.

Objective knowledge. Dissatisfaction with this approach subsequently led Karl Mannheim (who in 1918–1919 had been acquainted with Lukács in Budapest but had not joined the communists) to develop the notion of the intelligentsia as a privileged floating stratum. Mannheim, like Lukács, had originally been induced by his reading of Weber and Simmel to question the possibility of objective truth in historical and social matters. As he saw it, all sociological statements were hopelessly compromised by sectional and party standpoints. Unlike Lukács, he did not seek a solution by identifying a particular standpoint (that of the rising proletarian class) with the attainment of absolute or objective insight. Rather, he contented himself with allotting to the intellectuals as a group the task of criticizing the sectional viewpoints of the major social classes. Lukács's work provided the chief stimulus for Mannheim's *Ideology and Utopia*, and in this sense he may be said to have been an important link between the sociology of Weber and Simmel and what later became known as *Wissenssoziologie*. But whereas Mannheim's “relational” doctrine seemed to issue in a species of relativism, Lukács retained the notion of a privileged intellectual standpoint, historically conditioned indeed (as all forms of thought must be), yet certifying its superiority over rival standpoints by virtue of its unique possession of insights enabling it to comprehend both its epoch and itself. Here we see the Hegelian heritage which had originally attracted the youthful Lukács to Marxism and subsequently to Leninism as the contemporary form of Marxism.

All of this was too Hegelian for Soviet Marxists

and their east European followers, yet it was also incompatible with what Lukács termed "bourgeois empiricism." Mannheim and others although personally and doctrinally sympathetic to socialism, rejected the Hegelian-Marxist notion of a truth about history independent of, and superior to, the insights available to empirical sociology. The Marxian rejoinder (anticipated by Lukács in 1923) was to assert that, in thus rejecting philosophy, the sociology of knowledge had also relinquished the notion of an objective truth about history and society, leaving only partial truths relative to the standpoint of the observer and therewith seemingly opening the road toward a skepticism as boundless as it was hopeless. This theme was revived in the West after 1945, when impatience with the prospect of endless and pointless data accumulation carried a number of writers at least halfway toward the Hegelianized Marxism of the early Lukács—a tendency particularly marked among the Neo-Hegelian and Neo-Marxist schools in France and Italy.

In the central European context, the passions stirred by the 1923 controversy continued to be felt in the writings of Lukács's fellow heretic, Karl Korsch. They have likewise echoed in the historical and sociological studies published before and after the Hitler era by the scholars associated with the Frankfurt Institut für Sozialforschung—notably Max Horkheimer, T. W. Adorno, and Herbert Marcuse. The influence of the early Lukács is also discernible in the writings of such a noted literary critic of the Weimar period as Walter Benjamin, while a more distant echo may be discerned in the work of émigré scholars such as Leo Lowenthal of the University of California at Berkeley. From central Europe, the message of Lukács's Hegelianized Marxism was carried to France by the Rumanian-born scholar and literary critic Lucien Goldmann, whose studies of Pascal and Racine acquainted the French academic world with a new manner of treating literary subjects. Some of Goldmann's conclusions had been anticipated in 1934 by the Vienna-born scholar Franz Borkenau in an important, although neglected, work, *Der Übergang vom feudalen zum bürgerlichen Weltbild*. In contrast, Lukács paradoxically has not exercised any profound influence upon the younger generation of Marxist writers in central and eastern Europe since 1956. In general they have found him too orthodox for their taste and in particular too deeply wedded to the Leninist notions current in Soviet literature. These "revisionist" writers (e.g., the Austrian Ernst Fischer) tended to go beyond Lukács

in trying to construct a specifically Marxist doctrine of the social relevance of art. In philosophy, too, it was the existentialism of Sartre rather than the work of Lukács which, after the post-Stalin "thaw" of 1956, enabled the younger east European Marxists (e.g., the Polish writer Leszek Kolakowski) to free themselves from the ideological trammels of Leninism.

LUNDBERG, GEORGE

George Andrew Lundberg (1895–1966) was a vigorous and influential advocate of the pursuit of sociological knowledge by the method of natural science. Much of his writing was devoted to stating and clarifying the postulates of scientific thought, the fundamental attributes of objective research, and the applicability of such principles to sociological inquiry. He dedicated his academic career to the view that there are no characteristics of social phenomena and no features of scientific method that would preclude rigorous adherence to that method in the investigation of those phenomena. He gave particular emphasis to two implications of this position. First, he insisted that quantification of sociological concepts is possible and that great effort should be devoted to it. Second, he consistently argued that the achievement of scientific competence requires that sociologists learn to abandon traditional moralistic orientations toward their subject matter (Lundberg et al. 1929, pp. 403–404).

During his lifetime great strides toward quantification were taken which Lundberg credited

chiefly to the impact of successful empirical work, such as demographic studies, rather than to any methodological arguments (1944a, p. 7). He was far from sanguine in his last years, however, regarding the emancipation of contemporary sociologists from a legalistic–moralistic mode of thought, and this alleged bondage became the central issue of his final polemics.

Lundberg's positivism

Lundberg asserted that not all words have empirical referents but that people have responded to them as if they did. The alleged distinction between the "tangible" subject matter of the physical sciences and the supposedly "intangible" subject matter of the social sciences is merely a reflection of the differential advancement of observational and symbolizing techniques in the two fields; it is not an intrinsic difference in the respective classes of events being observed. Nothing essential is "left out" when we study societal phenomena objectively, although we often mourn the loss of feelings that were associated with familiar but ambiguous terms we have had to abandon. The operations by which we measure characteristics of the phenomena we study constitute definitions of those characteristics. The same phenomena may be studied according to various frames of reference, but these will lead to different conclusions.

Exclusion of value judgments. Lundberg's conceptual approach was similar to that of the Vienna circle, but he arrived at it independently. He attempted to show that all too many of the familiar-sounding terms in the sociological vocabulary were the sociological equivalent of the early chemist's phlogiston—no more necessary to describe or explain social phenomena than phlogiston was to account for combustion.

The sociologist's central task, he said, is to gather reliable data and from them to state principles—i.e., predictable sequences of behavior within highly standardized situations. Such principles can then be used to explain events in other situations whose significant departures from the standardized situation can be measured.

To be scientific, our analysis must be nonteleological. The physical sciences do very well without the concept of values, Lundberg said, but social scientists persist in transforming the verb "valuating" (which refers to discriminative or selective responding) into a noun, "values," and then they hunt in vain for its ostensible referent (1941a, p. 351). When critics accused him of "leaving out" what is essentially human, Lundberg replied that

he was not denying the occurrence or importance of value judgments but only insisting that they are a kind of behavior and that standards of value are inferences from behavior. Thus defined, values are not inaccessible to scientific study (1941b, p. 84). Men have always had visions of the good life, and these have helped to shape human actions. Reliable assessment of the changing content of such visions is a prerequisite to their effective public implementation, and there now exist scientific procedures by which one can do this assessing better than it is done by traditional methods (1950a, pp. 110–111). Lundberg offered specific proposals for the study of human values (*ibid.*, p. 105), but he continued to be accused of advocating a sociology that would "omit" this indispensable concept.

For some, this accusation gained plausibility from his perennial insistence that no science tells us what to do with the knowledge it creates. Scientific conclusions are statements of the probability of certain occurrences under clearly specified conditions, but they do not contain assessments of the "goodness or badness of the sequences described, apart from specified standards. The crucial point is that these standards are not themselves set by the scientific methods that result in the conditional scientific statements" (1950b, p. 265).

Social science and citizenship. In his presidential address to the American Sociological Society during World War II, Lundberg adamantly maintained that "it is more important than ever that we should not let the priority of our duties as citizens blind us to our functions as scientists" (1943a, p. 69). As a means of winning the war it was probably necessary, he conceded, to fabricate seriously distorted pictures of the world and of the nature of the enemy. Unfortunately, such pictures would persist, at least in part, for some time after the war and would influence the structure of the peace settlement. With a peace founded on illusion, another war was rendered likely (1944b, p. 89). It was vital that *social scientists themselves* not mistake the distortion for truth. Some of his statements illustrating this point were offensive to certain members of his audience and may have obscured his main message—that social scientists could hope to command public respect and thus be effective in an advisory role in regard to the peace settlement only if they were to demonstrate their scientific competence and objectivity (1944a, pp. 1–2).

Mindful of the impatience of others, Lundberg responded to the cliché that objective pursuit of abstract knowledge in such a crisis was like "lecturing on navigation while the ship goes down."

Because some men were content to keep on studying while their personal ships sank, he said, we have today some accumulated knowledge of navigation. We would not, had they joined the clamor for "short cuts to salvation whenever a storm occurred" (1943b, p. 199).

What bothered Lundberg most was the superficiality of the commitment of so many social scientists to the thoughtways of science. He lamented that in times of crisis many of us easily slip back "into the familiar personalistic-dramatic pattern of theology in which the forces of Good and Evil under their respective personal leaders again struggle for mastery" (1941b, p. 93). Not all scholars agreed with him when he spoke of the "theological and metaphysical nonsense" characterizing wartime discussions of "a highly subjective and relative concept called freedom." He held that "men are free when they feel free. They feel free when they are thoroughly habituated to their way of life" (1944a, p. 4). But some of his audience apparently felt dissatisfied with such a relativistic notion of freedom.

His unconventional views—for example, he had the temerity to argue that the understandable Jewish hostility to the German government exacerbated that government's hostility toward Jews—led to accusations that Lundberg had an anti-Semitic and profascist outlook, a product of his sociological positivism (Hartung 1944, pp. 340–341). If fascism means government by a self-appointed elite that suppresses all expressions of opposition, the accusation was clearly contradicted by Lundberg's lifelong insistence on the importance of distinguishing the role of scientist from the role of citizen and giving the scientist, in his role as citizen, no greater voice in public policy making than might be ascribed to by other citizens (1949, p. 10).

There is some indication that the accusation of anti-Semitism may have influenced Lundberg's subsequent choice of research topics, for although he had studied patterns of status differentiation and preferential association in the prewar years, he had not done previous research on minority groups as such or on ethnocentrism (Lundberg & Steele 1938; Larsen 1965a). He turned to these topics after the war, as if to substantiate his contention that moralistic and legalistic biases had heretofore tended to limit social science inquiry into these matters. As Lundberg saw it, numerous Jewish organizations striving to combat anti-Semitism pursue policies which actually aggravate it (1944c). The preventive for such ill-conceived programs is more adequate and more reliable knowledge, to which

Lundberg proposed to contribute (Lundberg & Dickson 1952).

Career and influence

Lundberg's polemics, less than persuasive to his accusers, were not his sole preoccupation in the postwar years. He also coauthored one of the leading introductory sociology textbooks (in its third edition at the time of his death), and he served as chairman of the department of sociology at the University of Washington during a period of rapid expansion of its faculty, its graduate program, and its research activities. Other facets of his postwar activities included writing the popular book *Can Science Save Us?* (1947) and editing a sociology series for a book publisher. Lundberg lectured on, and helped to promote, sociology in the Scandinavian countries, and, after concluding his administrative role at the University of Washington, he continued to teach there for a number of years before he retired. He was in demand as a lecturer at various universities and before nonacademic groups as well.

Before assuming the chairmanship at Washington, Lundberg had been on the faculties of the University of Pittsburgh, Columbia University, and Bennington College and had held appointments at Stanford, Brigham Young, and Minnesota. He had held research positions with federal and local welfare agencies and had been elected president of the Sociological Research Association and two regional sociological societies, as well as the American Sociological Society.

Lundberg was a graduate of the University of North Dakota, which also awarded him an LL.D. in 1958. He held the M.A. degree from Wisconsin and the Ph.D. from Minnesota, which also awarded him its Distinguished Achievement Medal in 1951. He was editor of *Sociometry* from 1941 to 1947 and wrote some seventy articles, as well as several influential books.

At the time of Lundberg's retirement, Paul H. Furfey, one of his staunchest intellectual adversaries, paid him this tribute: "He has always made it seem obvious that winning an argument is unimportant, but that arriving at the truth is supremely important" (Larsen 1965a, p. 26).

LUTHER, MARTIN

Although the Reformation was in its purest essence a religious movement, from the outset it also involved social, political, and economic forces and effected fundamental changes in many areas of life. The first of the magisterial reformers, Martin Luther (1483-1546), was pre-eminently concerned with theological matters, but his evangelical insight into the deepest meaning of the Christian gospel had tremendous implications for all aspects of social life and theory. Throughout his life he gave evidence of his concern for social action.

The operative principle of Luther's social ethics,

as expressed in his treatise entitled *Christian Liberty* (1520), was that religious faith must be active in love. The person precedes the action, for, as he asserted, "good works do not make a good man, but a good man does good works." The new spiritual life of a man who has come to a trusting faith in the gracious God revealed in Christ produces in him a spontaneous outflowing love for his fellow man. This love far transcends a mere prudential desire for the highest good and, like God's love, should not be dependent upon the worthiness or loveliness of the object. This ethical principle intensifies the force of conscience and the inner-directedness of the Christian in society, minimizing heteronomous controls.

Luther believed that all reality belongs to God's realm, for in the church God works through the Word of the Gospel for the spiritual good of man, and in the secular orders God works through men for the temporal good of man. Thus, such natural orders as the family, the various vocations, the state, and the organization of society in general are also divine orders. While historically they have shown development and are structurally subject to change, these natural orders have their origin in the divine will and are divinely ordained. This view allowed Luther to transcend the negative assessment of secular institutions characteristic of much medieval thought. Institutions such as marriage and state authority had been viewed merely as restraints necessitated by sin or as systems whose legality depended upon the sanction of the church. He viewed them positively as instruments of God's love and urged men to be thankful for them and to sustain them.

Luther held natural law to be the basis of the natural orders and of all secular authority, including that of non-Christian rulers. He understood this natural law to be the law of love implanted in man's consciousness and more clearly revealed in the Decalogue and refined in the Sermon on the Mount. Since communities are of divine ordinance, their good positive laws cannot be contrary to God's will; these laws are rooted in natural law and have a theonomous, or divinely obligating, character. Luther stressed emphatically the need to keep separate the secular and spiritual authorities, for the state is an authority that wields power and is exclusively concerned with the temporal order, while the church is a communion or priesthood of all believers responding to the gospel of God's love.

Luther's view of society and of man's culture, then, was dialectical. On the one hand, culture and society are theonomous insofar as they are sustained by the ever-present creative action of God,

who initiates all, encompasses all, and rules over men. On the other hand, they are autonomous insofar as they are the product of man's own free, rational, responsible, cooperative action. Christians moved by love should participate in the social order and mend and improve it for the good of mankind. Because of his own foreshortened eschatology and preoccupation with ecclesiastical concerns, Luther did not invest effort in the systematic renovation or reorganization of society, as Calvin did, but his thought contained the basic elements for a constructive social philosophy.

In addressing himself to specific social issues, Luther at times reflected conservative views of long standing and at other times expressed novel ideas, which were ahead of his time and which found echoes in subsequent theorists. Although he was himself the son of a rising middle-class mining entrepreneur, he believed in the superior virtues of agrarian life over commerce. He opposed usury with vehemence and flayed the monopolies of ruthless large capitalists like the Fuggers and Medicis. He argued for the just-price theory and accepted the labor theory of value. He stressed the value of vocation to the active life and raised the *ordo naturalis* to the dignity of the *ordo spiritualis*. He opposed the mere giving of alms to beggars and urged that people sunk in poverty be given the means to help themselves. While encouraging support of the government and military service in the case of a just war of defense against an aggressor or an international lawbreaker, he insisted that under absolutely no circumstances could a Christian serve in an unjust cause or against his own conscience. It would seem that the highly organized and welfare-oriented social philosophies of such Lutheran lands as Denmark, Sweden, Norway, and Finland reflect generically the basic social thought of Luther. His pivotal faith in God gave him a certain detachment toward material wealth and a courageous attitude in the face of hostile political power and military threats—qualities that perhaps retain a basic relevance for modern social thought.

LUXEMBURG, ROSA

Rosa Luxemburg (1870-1919) was one of the founders of the Social Democratic party of Poland and Lithuania, the leader of the left wing of the Social Democratic party (SPD) in Germany, and a prominent Marxist economic theorist. She was born in Zamosc but spent her childhood and youth in Warsaw. She came from a family of Polish-speaking Jewish merchants, and her mother brought her up in a liberal atmosphere, instilling in her a love of classical German culture. She grew up in a period when the tsarist government was increasing its political and religious oppression and when socialist activity was beginning in Poland.

While still in high school Rosa Luxemburg became active in the socialist movement, and in 1889 she was forced to flee abroad. She entered the University of Zurich with the intention of studying natural sciences but soon shifted to political economy. In addition to the university program, she studied the works of Adam Smith, Ricardo, Rodbertus, and, above all, Marx. In her doctoral thesis, *Die industrielle Entwicklung Polens* (1898; "The Industrial Development of Poland"), she argued that the development of industrial capitalism in the Polish kingdom depended heavily on the Russian market and that the economy of the Polish kingdom would never be more than a part of the tsarist economy. The analysis in this book formed the basis upon which the Polish Social Democratic party built its political program.

In order to be able to take part in the German socialist movement, she acquired German citizenship through a fictitious marriage with a German emigrant. From 1897 until her death she lived, except for short intervals, in Berlin.

Immediately upon her arrival in Germany she joined Karl Kautsky in the fight against Eduard Bernstein and his revisionist followers. Bernstein's thesis, "The movement is everything, the aim nothing," was incompatible with her belief that the struggle for political power was a necessary aim of

the socialist movement. Her essays criticizing Bernstein's economic and political doctrines were collected in *Reform or Revolution* (1899).

In 1905 she returned to Warsaw under an assumed name to help the revolutionary movement there but was soon arrested. After her release from jail she went first to St. Petersburg and then to Finland, where she wrote the pamphlet *Massenstreik, Partei und Gewerkschaften* (1906; "General Strike, Party and Trade Unions"). The work contains a sociological analysis of the driving forces of social revolution and its mechanism—an analysis, on the one hand, of the role of the masses and, on the other hand, of the organization and role of the leaders. In this pamphlet she also developed the view that the general strike is the fundamental instrument in the struggle of the working class for power.

As the orthodox Marxists discussed their revolutionary experiences, particularly their experiences with political strikes, essential differences among them emerged. This led to a break between Luxemburg and Kautsky, which meant that the German Social Democratic party became divided into three groups: a right wing led by Bernstein, a center group led by Kautsky, and a left wing led by Luxemburg.

Beginning in 1907 she lectured at the Berlin school of the Social Democratic party. Both her earlier lectures on political economy and her later ones on economic history were published posthumously from her manuscripts, with the title *Einführung in die Nationalökonomie* (1925). Her most famous economic work, *The Accumulation of Capital* (1913), also grew out of these lectures.

The Accumulation of Capital may well be Luxemburg's most important contribution to the social sciences. The book has as its main theme the conditions of economic growth under capitalism, and its original contribution lies, therefore, in the field of economic theory. In Luxemburg's opinion, pure capitalism cannot create conditions adequate to maintain its own development. The main factor that gives capitalist production its dynamic power is the expansion toward noncapitalist areas, both underdeveloped countries and spheres of noncapitalist production within capitalist countries. This expansion comes about because capital accumulates, while at the same time demand within the capitalist society does not increase fast enough to absorb the increasing supply of goods.

During the imperialist phase of capitalism this difficulty is solved by the production of arms. The arms not only absorb domestic capital but also help

create new markets in the colonies. The state's customs and tax policies also play an important part in the economic development of capitalism, especially in the period of imperialism. Luxemburg saw free international trade as only an episode in the history of capitalism and criticized Marx for disregarding the historical conditions that affected the accumulation of capital; she charged Marx with considering historical conditions important only in relation to the birth of capitalism and exclusively with reference to private accumulation. Luxemburg believed instead that the relations between capitalism and its precapitalist surroundings constitute a source of tension and international conflict. These lead to a series of wars and social revolutions that in turn start the process of the decline of capitalism. In the history of Marxist economic theory Luxemburg's work on the accumulation of capital has produced much theoretical and political polemics.

Initially, the reactions to *The Accumulation of Capital* were negative. Such theorists as Karl Kautsky, Otto Bauer, and Nikolai Bukharin not only rejected the major theory of the book but even questioned whether the problems investigated by Luxemburg were important ones. The first work in the literature of economics seriously to consider as well as to extend Luxemburg's theory of accumulation was Fritz Sternberg's *Der Imperialismus* (1926). Only with the Keynesian revolution was Luxemburg's theory, that lack of purchasing power causes a breakdown in the capitalist system, rehabilitated.

Luxemburg was again imprisoned during World War I, this time for her antimilitary activities. She devoted the three years she spent in jail to theoretical and journalistic writing. She wrote a book answering the critics of *The Accumulation of Capital*, a brief work on the crisis of social democracy (known as the "Junius Pamphlet"; see Luxemburg 1916), and the unfinished manuscript from which the posthumously published *Russian Revolution* (see in 1904-1922) was drawn. *The Russian Revolution* is one of the most controversial works in socialist political literature, where it occupies a position similar to that of *The Accumulation of Capital* in economic literature. Luxemburg acclaimed the October Revolution as the most important result of World War I, but this did not prevent her from criticizing Bolshevik practice. Thus, she deplored the fact that the postrevolutionary political system was a dictatorship not of the masses, but over the masses. She was disappointed that the large landholdings had been divided among the peasants, for she felt that this created a new and powerful class

of proprietors, i.e., enemies of socialism. She also disapproved of Bolshevik policy toward nationalities.

Upon her release from prison at the end of 1918, Luxemburg immediately joined the German revolution. Late that year she and Karl Liebknecht together founded the German Communist party and wrote its program. They were both arrested early in 1919 and were both assassinated by the soldiers in whose custody they had been placed.

M

MACAULAY, THOMAS BABINGTON

Thomas Babington Macaulay (1800–1859), English historian, essayist, and politician, was born at Rothley Temple, Leicestershire. His father, Zachary, one of the leading members of the “Clapham sect,” was a stern evangelical who fought unremittingly for the abolition first of the slave trade and then of slavery itself. Macaulay’s mother was the daughter of a Quaker bookseller and herself a devout evangelical. Thus, the young Macaulay, an astonishingly precocious boy, grew up in an atmosphere of piety, introspection, and humanitarian endeavor. He absorbed and retained the moral and ethical imperatives inculcated upon him; but much to the chagrin of his father, he never underwent a conversion experience and always remained wary of the emotional excesses, cant, and hypocrisy to which an experiential religion so easily lends itself.

At Trinity College, Cambridge, he distinguished himself as a classicist and a poet. He became a fellow of the college in 1824. While at the university, he triumphed as an orator in the Union Debating Society and began his brilliant career as an essayist. In the latter role, he first made his mark with his essay “Milton,” which appeared in the *Edinburgh Review* of October 1825 ([1825–1844] 1963, vol. 1, pp. 150–194). It was indeed appropriate that in that essay, which made him famous overnight, he should have taken his place on the libertarian side of seventeenth-century English politics. Although Macaulay had been a mild Tory when he entered the university, he was a staunch Whig when he left, and in many ways his political stance was derived from his study of the constitutional conflicts of the seventeenth century.

In “Milton” and subsequent writings he transferred the theme of those conflicts to the decade of struggle between Whig and Tory before the passage of the Reform Act of 1832.

His early essays in the *Edinburgh Review* are richly caparisoned with wit, paradox, and antithesis, but as Bagehot justly remarked, “Macaulay is anything but a mere rhetorical writer, there is a very hard kernel of business in him.” What gave his writings this “kernel of business” was his sturdy common sense, his fondness for Baconian induction, his suspicion of system making and *idées reçues*, and his ability to get to the root of the matter. These characteristics led him on occasion to anticipate some of the insights of twentieth-century social science; the results are still well worth sampling in some of his articles: “Thoughts on the Advancement of Academic Education in England” (1826), in which he presented a well-argued case against the collegiate system of Oxford and Cambridge and for a nonresidential university in an urban setting; “Social and Industrial Capacities of Negroes” (1827), in which Macaulay saw the roots of the Negro problem as fundamentally social and economic rather than in any sense innately “racial”; “Machiavelli” (*The Works of Lord Macaulay*, vol. 7, pp. 63–113), which, as Paul Lazarsfeld has pointed out (1957), contains an account of what is probably the first projective test recorded in the literature; “History” (*Works*, vol. 7, pp. 167–220), which makes an excellent case for writing the history of societies as a whole, rather than of wars, battles, diplomacy, and politics; “Mill on Government” (*Works*, vol. 7, pp. 327–371), which argues against the utilitarian theory of government persuasively enough to have convinced John Stuart Mill himself; and “Civil Dis-

abilities of the Jews" (*Works*, vol. 8, pp. 1-17), which brilliantly places the problem of anti-Semitism into a historical context.

Macaulay was elected to Parliament in 1830. His speeches in favor of the Reform Bill in 1831 and 1832 gained him immense repute as an orator and secured for him, an outsider who lacked both wealth and noble birth, entry into the strongholds of Whig society. For him parliamentary reform was not merely a matter of expediency, although, to be sure, he emphasized that the aristocracy had better make timely political concessions to the middle classes if it wanted to avoid revolution. Reform was, rather, the latest inevitable stage in a series of historical developments that had resulted in a more widespread distribution of property, great increase of wealth, ever greater triumphs of science and industry, and a steady progress from rudeness to refinement. In other words, the Reform Act was merely one way of bringing political arrangements into alignment with an advancing state of society.

In 1834 Macaulay went to India as a member of the governor's Supreme Council. His personal motive for going was to make himself financially independent. In India he made two significant contributions. In 1835 he wrote the historic and still controversial "Minute on Indian Education" ([1831-1853] 1935, pp. 345-361), which proposed English as the principal language of instruction for any national system of education in India, so that Western science, culture, and technology could more easily be transmitted. And he was largely responsible for drawing up a uniform Indian penal code in 1837. Its substance was the English criminal law. Revised by Sir Barnes Peacock, it went into operation in 1862.

In 1838 Macaulay returned to England, and it was in the course of that year that he began seriously to plan his major literary work, which eventually appeared under the title *The History of England, From the Accession of James the Second, . . .* (1848-1861). He remained active in politics, was Secretary at War from 1839 to 1841, and sat in Parliament for most of the rest of his life.

The first two volumes of the *History* came out late in 1848, and it was appropriate that a work celebrating the bloodless revolution of 1688 and the establishment of English constitutional stability should make its appearance in the course of a year that had seen revolutionary violence on the continent of Europe, but not in England. In his *History* Macaulay showed himself to be a master of historical narrative.

The tour de force of the *History* is undoubtedly

"England in 1685," the first volume's famous third chapter which in the space of 150 pages surveys the nation's geography, population, resources, means of transport, and varied social classes and their occupations, as well as its army, navy, science, literature, and press. It is descriptive rather than analytical social history. Still, of its kind and of its time it remains a magnificent achievement.

The *History of England* is not without its defects. Macaulay's historical imagination was strong but limited. He approached the past from the vantage point of a more glorious present. He was, as S. R. Gardiner pointed out, a better judge of situations than of character. There are some distortions. But those who expect to find in the *History* a naively stated *parti pris* will look in vain.

The popular success of the *History* (volumes 3 and 4 appeared in 1855, a fifth volume posthumously in 1861) was immense and constituted a unique publishing phenomenon in nineteenth-century England. It appealed to the pride as well as the prejudices of its purchasers and was read with both pleasure and profit by an ever-growing literate public. In historiographical terms it marked, as Leopold von Ranke observed, the triumph of the Whig view of seventeenth-century English history over the Tory view, articulated by David Hume. But the recent tendency to categorize and then dismiss Macaulay as a "mere" Whig historian is giving way to a more balanced sense of his achievement.

Macaulay was awarded a peerage in 1857, the first English historian to be so honored.

McCULLOCH, JOHN RAMSAY

John Ramsay McCulloch (1789-1864), economist and statistician, was born in Scotland, the son of a small landowner. He studied law in Edinburgh but soon abandoned that field in favor of political economy. His first publication, which appeared in 1816, called for a reduction of the rate of interest on the national debt on both theoretical and practical grounds and led to a correspondence with Ricardo. When Ricardo's *Principles* appeared in 1817, McCulloch immediately supplied a masterful digest of the book to the *Edinburgh Review*, the most popular quarterly of the day. For the next twenty years almost every issue of the *Review* carried an article by him. At the same time, he contributed to the *Scotsman*, and from 1818 to 1820 he edited this famous liberal paper.

In 1820 he went to London, where he taught economics privately. After Ricardo died in 1823, his friends and admirers chose McCulloch to deliver the Ricardo memorial lectures at a privately rented hall. These lectures were expanded into an outline of basic principles in the article on political economy for the new edition of the *Encyclopaedia*

Britannica (1824a); in this article McCulloch equates Ricardo's brand of economics with the science itself. It was succeeded by a formal treatise, *The Principles of Political Economy* (1825), a work which had considerable vogue until J. S. Mill's work of the same title (1848) supplanted it. There followed *A Treatise on the Circumstances Which Determine the Rate of Wages* (1826), to which the Webbs later drew attention by calling McCulloch "the inventor of the wages fund doctrine" (Webb & Webb 1897). However, this doctrine is to be found in Adam Smith's writings, as well as in Ricardo's, and McCulloch did not contribute anything new to its presentation.

Academic security eluded him all his life. In 1828 he was appointed to an unendowed chair at the newly founded University College in London. He resigned the position in 1832 because no donor had come forward to endow the chair. Earlier an attempt to make him the first incumbent of a new chair of political economy at the University of Edinburgh had also been unsuccessful. At last, in 1838 he obtained a lifetime sinecure as comptroller of Her Majesty's Stationery Office. He took little part in the activities of the department and, although he had by then abandoned journalism, he continued to publish books and pamphlets on economic subjects.

It was McCulloch, more than any other man, who was responsible for Ricardo's enormous influence upon the economic thinking of the times. He was, however, more than Ricardo's spokesman; he was the greatest economic publicist of his day—so much so that all those who detested political economy invariably selected him as their whipping boy. He appears, Scots accent and all, as "McGroudy" in Carlyle; as "MacFungus" expounding "econoomical science" in Peacock; and as "The Scot" in that old Victorian favorite *Noctes Ambrosianae*, by Christopher North. Today he is chiefly remembered as a prime example of the zealous, dogmatic disciple. But devoted disciple though he was, he did not endorse all of Ricardo's opinions: he condemned Ricardo's *volte face* on the question of technological unemployment; he never fully accepted the theory of comparative advantage; and he always qualified Ricardo's theory of profit. In later years he openly admitted defects in the Ricardian system.

An indifferent theorist, McCulloch appears at his best in his statistical and descriptive compendia rather than in his theoretical writings. His *Dictionary . . . of Commerce and Commercial Navigation* (1832), much of which was embodied in his later treatise *A Descriptive and Statistical Account of*

the *British Empire* (1837), demonstrated his encyclopedic knowledge of the British economy, and it remains to this day an authoritative reference work. Moreover, he deserves to be regarded as the first professional historian of economic thought. A *Discourse on the Rise . . . of Political Economy*, first published in 1824 and then appended to his *Principles*, was the first attempt in any language to project a formal history of this subject. Later contributions to the historiography of economics consisted of an edition of Adam Smith's *Wealth of Nations* in 1828, with copious notes; an edition of the works of Ricardo in 1846, with a famous biography; numerous reprints of scarce tracts; and a celebrated *catalogue raisonné*, *The Literature of Political Economy* (1845a), based upon his own magnificent collection of economic works.

Unlike other members of Ricardo's circle, McCulloch did not subscribe to radicalism in politics, nor did he share the utilitarian enthusiasm for land reform. His outlook was that of a liberal Tory, optimistic but conservative. He always took exception to the gloomy implications of the Malthusian theory of population. He hesitated to condemn the poor laws entirely and, in contrast to most other economists of the day, disapproved of the Poor Law Amendment Act of 1834. Although a convinced free trader, he never joined Richard Cobden and John Bright in demanding immediate and total repeal of the corn laws. In his days as a journalist, he achieved notoriety as an apologist for the new factory system, but in later years he grew increasingly uneasy about the consequences of the industrial revolution.

MCDUGALL, WILLIAM

William McDougall (1871-1938) occupies a position in the history of psychology that is not easy to define. During the earlier part of his working life he was a central figure, in touch not only with all that was going on in psychology but also with anthropology and physiology as well. As time

went on certain qualities of character and intellect tended to isolate him, and before he died he had moved to the fringes of the academic world, writing largely for laymen and associated in the minds of his fellow scientists with a discredited instinct theory, Lamarckian genetics, and parapsychology. He was aware of this and felt it deeply. "Similar abilities, energy, and sustained effort, applied in any other line of work, might well have brought considerable reward," he wrote in his autobiography. "The more I write, the more antagonism I seem to provoke" (1930, p. 223).

McDougall was born in Lancashire, England. A precocious student, he graduated from the University of Manchester at age 17. Two years later he went to Cambridge to study physiology, then as now a common approach to a medical qualification. His M.B., which he took in London in 1898, was not intended to lead to work as a physician. He had a few months of physiological research with Sherrington before returning to Cambridge, where his brilliant academic record had brought him a fellowship at St. John's College.

Almost immediately he was involved in a scientific expedition to the Torres Strait. W. H. R. Rivers, who was to influence so many Cambridge men, asked him to carry out psychological observations on the natives, and his wide-ranging mind was soon at home in the anthropological literature of his day. Darwin's influence at that time must have been so pervasive as to be unrecognizable, yet looking back we can see that it was the primary source of McDougall's thinking in many fields. On an expedition such as that to the Torres Strait the zoologists and botanists must have had the *Voyage of the Beagle* very much in mind, and the direction of their work was to identify the part played by various structures and activities in the adaptive economy of the species in which they occurred. This kind of interest, when it arises in psychology, forms part of the viewpoint which has been called functionalism to distinguish it from the psychological structuralism of Wundt and the quasi-physiological theories of behaviorism. It dominated the Anglo-Saxon world for a time and received its clearest expression in William James's great *Principles of Psychology*.

Returning to Cambridge, McDougall sampled the German and British philosophical psychologists of his period. Lotze attracted him but Wundt did not. The former was philosophical and tentative in his approach, with a bias against mechanism and an interest in psychological functioning; the latter was dogmatic in his claim that mental content is the only valid subject matter for psychology. On

the advice of James Ward, professor of moral philosophy at Cambridge, McDougall went to Göttingen and studied under Georg E. Müller. He did not become a disciple but was attracted to color vision research. His work led him to reject the theories both of Hering and of Helmholtz, but his own theory did not constitute a major departure. Rather it was an attempt to supplement the views of Helmholtz so as to accommodate Hering's findings, by adding an evolutionary footnote. If McDougall had formulated his suggestion somewhat differently, as others did at the time, it would be acceptable today. [See VISION, *article on COLOR VISION AND COLOR BLINDNESS*.] At the same time he was concerned with the general nature of cerebral activity; here his views tended toward the theory, first put forward by Flourens, that the brain does not function as an enormous collection of individual pathways but is a unitary organ acting as a whole. This "mass action" theory may best be thought of as a protest against oversimplification. McDougall also displayed an interest in the relationship between mind and body which persisted throughout his life. He took a dualistic line and suggested that mental events as such may influence bodily processes. His views were unfashionable then, and, despite the rise of psychosomatic medicine, they have remained so. [See NERVOUS SYSTEM; PSYCHOSOMATIC ILLNESS.] They were also undoubtedly linked with his emerging interest in psychical research. He related his views in this connection to his "uncompromising arrogance" and to his inclination to support a theory merely because it was unpopular.

In 1904 McDougall went to Oxford as Wilde reader in mental philosophy. He had to give some forty lectures a year on topics of his own choosing, and the rest of the time was his own for research and writing. He did not feel at home in the Oxford atmosphere, but he did have a small laboratory in the department of physiology and some outstanding research students, including Cyril Burt and J. C. Flugel.

Some of his best work belongs to this period. His little *Physiological Psychology* appeared in 1905. It is not read now because later techniques and theories have dated it, but within its scope it was an admirably clear and objective piece of work, and its qualities highlight the diversity of McDougall's talents at this stage of his career. [See PSYCHOLOGY, *article on PHYSIOLOGICAL PSYCHOLOGY*.]

An Introduction to Social Psychology was published in 1908, and in it McDougall first propounded his influential instinct theory. The book ran through more than twenty editions in as many

years and is perhaps as much undervalued today as it was overvalued then. In ethology and elsewhere, aspects of McDougall's position are now widely current, although restatement has done much to disguise them. To McDougall the fact that anthropologists could identify the adaptive role of social organizations and that zoologists could do the same for inherited patterns of behavior meant that at the human level also there is a mediating mechanism through which complex adaptive ways of behaving, both social and individual, can be transmitted, and that mechanism is instinct. An instinct, for McDougall, was not a built-in response pattern specified in detail—such as we see in the repertoire of solitary insects—but merely a tendency, under given conditions, to notice certain kinds of stimuli, to respond to them in ways that can best be specified by reference to some goal, and to experience a particular emotion if the response is delayed. Learning plays a great part in this mechanism both by diversifying and stabilizing the response. McDougall's later critics, using a much more limited definition of instinct, often did him an injustice by failing to give due weight to this last point.

The work was written rather quickly and was based on reading and reflection rather than actual research, but the argument was so persuasive that it soon established itself as one of the most widely read texts on either side of the Atlantic. The early acclaim for this vulnerable piece of work probably accounts in part for the vehemence with which it was later denounced. There also occurred during McDougall's lifetime, however, a change in the climate of opinion, which more than anything else was responsible for the curiously inverted nature of his career, with its early fame and later comparative obscurity. The functionalist approach, which derived from Darwin, became replaced by a more analytic and objective attitude. In psychology, the rise of behaviorism and associationist learning theory marked this change. McDougall found himself more and more out of step with his colleagues and, being the man he was, reacted polemically rather than creatively to the challenge.

Body and Mind, with its revealing subtitle, *A History and a Defense of Animism*, came out in 1911 and showed clearly that even before the rise of behaviorism there were expressions of hostility to mechanistic theories in the biological field. McDougall himself, who was not without insight into his own foibles, described the work as another characteristic championship of an unpopular view just because it was unpopular. Yet even then his

reputation as a scientist must have been very high. In 1912 he was elected a fellow of the Royal Society, one of the small number of psychologists ever to receive this honor.

World War I brought about some shift in the direction of McDougall's interests from pure research and speculation toward applied and clinical problems. Since he was medically qualified, it was natural that he should serve as a psychiatrist. Neither psychologist nor psychiatrist had much in the way of professional training in those days, and demarcation disputes did not arise. Many of the psychiatric casualties of World War I suffered from the hysterical condition known as shell shock. The methods which McDougall found most useful in treating psychiatric casualties confirmed his earlier belief in the value of Jung's work. He did not find it necessary to trace a breakdown to events in the early childhood of a patient but treated it as an inadequate reaction to an immediate situation. After the war he went to Jung in Zurich and underwent analysis. Writing of it later he said that his personality was so "hopelessly normal" that the process made very little difference to him. He remained, however, well disposed toward Jung.

In 1920 there appeared *The Group Mind*, a study in which the Darwinian ideas of the *Introduction to Social Psychology* were supplemented and elaborated by other ideas from analytic psychology and anthropology. It was conceived by its author to be the first part of his masterwork, and he had high hopes of being able to work out a single systematic treatment of his subject from its social and anthropological to its biological frontiers. His ideas, however, were far too speculative and his statement of them far too discursive to make what he had to say widely acceptable to his contemporaries. This seems to have been the turning point. Although McDougall was still to contribute much of value to psychology, the setback that he suffered at this stage seems to have done more than anything else to drive him into the byways. Although the size of his output remained considerable, its scientific content tended to decline.

It was perhaps a symptom of his unsettled state that he felt it would be a good idea to move from Oxford to Harvard. Münsterberg he had found congenial, and William James was probably, of all psychologists, the one he admired with fewest reservations. These were the names that represented Harvard to him, and he felt that he would find there a more sympathetic environment than anywhere else. It was an ill-judged move in many ways. The atmosphere had changed since the days

of James and Münsterberg, the administrative arrangements were not what he had supposed, and in his frustration he may well have alienated some of his colleagues.

He began some animal experiments to test the Lamarckian hypothesis, and he published during this period two considerable but little read books—*Outline of Psychology* (1923) and *Outline of Abnormal Psychology* (1926). In a few years, however, the difficulties of Harvard became oppressive, and he made his final move, to Duke University in North Carolina. Duke had been recently founded and richly endowed, and it seemed to promise the independence and financial support required by a research scientist and something of the isolation demanded by a prophet. At any rate the change was a happy one, and McDougall settled down in his new home as contentedly as he could anywhere. He carried on his Lamarckian work, he supported psychical research, he built up a good psychology department, and he published extensively on a wide range of topics. It is not unfair to say, however, that judged by contemporary standards nothing of this later work is of first-rate importance.

McDougall's dogmatism and impatience are partly responsible, no doubt, for the fact that despite his brilliant gifts and tremendous industry he felt himself to have been a failure. He did arouse hostility where he need not have done, and, as has been pointed out, he lived through a period of rapid change in biological science and was out of step with events. More basic, however, as a reason for his difficulties seems to have been an emotionally toned refusal to look at human beings with the detachment and objectivity of the scientist. He was always a moralist and sometimes a metaphysician, so that his conclusions were as often a function of his personality as of his data.

MACHIAVELLI, NICCOLÒ

Niccolò Machiavelli (1469–1527) was an Italian political and military theorist, civil servant, historian, playwright, and poet.

The Machiavellis, an ancient middle-class family of Florence whose income came from landed property, had been reduced to near poverty at the time of Machiavelli's birth. His father was a doctor of law. Machiavelli seems to have been carefully educated in humanistic studies, although he never learned Greek. He entered Florentine government service in 1498, at the age of 29, as second chancellor and secretary of the Ten of Liberty and Peace, an executive committee concerned with domestic as well as military and foreign affairs. During his 14-year tenure he was engaged in numerous and sometimes lengthy diplomatic missions which took him to France, Switzerland, and Germany. His dispatches and reports contain ideas that anticipate many of the doctrines of his later works.

Military affairs were a continuing preoccupation of Machiavelli's. Not only was the famous militia ordinance of 1506 his, but also the responsibility for implementing it, in the capacity of secretary of the specially constituted Nine of the Militia. When the Florentine government was threatened in 1512 with the restoration of the Medici by Spanish forces, Machiavelli skillfully mobilized an army of twelve thousand conscripts to withstand the invasion; however, the amateur citizen-soldiers proved ineffectual before seasoned troops.

With the restoration of the Medici, Machiavelli was briefly imprisoned and tortured. Upon release he was banished from Florence to live in impoverished retirement on the small estate his family owned at Sant'Andrea. After 13 years of political inactivity he was recalled to government service

by the Medici in 1525, but two years later the Medici were overthrown, and the new republic again excluded Machiavelli from office. He died in 1527, receiving the last rites of the church.

Machiavelli was a good father and an affectionate if unfaithful husband. Scrupulously honest, he was also generous and tolerant and had unusual courage and integrity. He excelled in witty conversation and storytelling. As much a poet as a man of practical affairs, he was a dedicated republican who desired only to serve Florence rather than any particular party. He was an extraordinary literary artist and has long been recognized for his masterful prose style; as the author of the comedy *Mandragola* (see 1509–1527) he has been acclaimed the equal of Molière.

Method. Machiavelli was neither a system builder nor a philosopher in a technical sense. In no single treatise did he rigorously expound his theory of man and government. His views are presented in a diffuse and impressionistic fashion, scattered through a number of different works. At the same time, there is system and remarkable consistency to his ideas, even if the coherence is not the most obvious and depends to a degree upon imaginative reconstruction by the sensitive reader.

Among Machiavelli's particular achievements was his attempt to discover an order in political activity itself, not in some external standard or cause. He examined politics in a detached, rational manner, analyzing the ways power can be acquired and maintained. He showed the kinds of actions that in varying situations will lead to political success or failure. Although he was not concerned with moral and political obligation or with the analysis of moral and political concepts, a conception of a good society does inform most of his political writings.

The sources of his approach are a matter of conjecture. He probably owed less to the traditional philosophers than to nonphilosophical classical writers—in particular, to Livy, Tacitus, Plutarch, Xenophon, Polybius, Vegetius, and Frontinus. Machiavelli was not alone among his contemporaries in abandoning a moralistic approach to human behavior for a rational and objective one: the influence of Platonism resulted generally in increasing efforts to reduce activity to an inherent order and these efforts in turn led to the scientific revolution of the seventeenth century (Cassirer 1927). That Machiavelli lived in a city whose very life was finance and commerce may also help to explain his method, which had some of the characteristics of a business calculation of profit and loss. Another possible influence was the increasing conceptual-

ization of government policy, since the thirteenth century, in terms of a notion of public utility: the Holy Roman Emperor Frederick II (1194–1250), Philip IV of France (1268–1314), and some Italian legalists held that the security and well-being of the state at times necessitated official acts which under ordinary circumstances would be considered morally reprehensible. Machiavelli was heir to this late medieval tradition.

Machiavelli was essentially concerned with ascertaining the conditions of political success, and he sought to do so by determining what kinds of acts have proved beneficial and what kinds detrimental to the (political) actors who performed them. In *The Prince* and the *Discourses*, written between 1513 and 1521 (see 1532a), he demonstrated the soundness of certain political precepts by using a kind of calculus: he cited numerous examples, drawn from history and from the events of his own time, that would support a particular proposition about the conditions of political success, and he then searched for further examples that would appear to negate the same maxim; only after careful scrutiny of the "negative" cases did he decide whether they really were in fact negative or only appeared to be so because of very different circumstances. He used this method for military precepts, in these works and in *The Art of War* (1521). Again, his penchant for discovering general patterns is evident in his *History of Florence*, completed in 1525 (1532b), in which he sought to establish causal relationships in place of mere chronology. It is a pioneer work in modern western European historical writing.

The inspiration for the method may well have been two books with which he was familiar—the *Dictorum factorumque memorabilium* of Valerius Maximus, a compendium of ancient examples to illustrate human behavior, which was dedicated to the first century emperor Tiberius, and the *Strategemata* of Frontinus, a catalogue of military stratagems of the latter part of the same century. Whatever the sources, the method differs markedly from that of classical and medieval political theory. In a way, Machiavelli's approach anticipates the inductive method of Francis Bacon, which, much like an adversary proceeding, entails the collection of positive and negative examples and their resolution.

Theory of man. Crucial to Machiavelli's political theory is his concept of man's nature. From his own shrewd observation and omnivorous reading of history, he concluded that man's nature is changeless—were it not changeless, generalizations about politics could not be made—and that it is essen-

tially evil. (Unlike Plato and Aristotle, Machiavelli used the concept of human nature in a descriptive rather than a normative sense.)

Man's innate evil qualities are such, however, that they do not preclude the possibility of cooperative human endeavor; indeed, some of these very qualities facilitate social cooperation. Man's basic traits are the following: he is a creature of insatiable desires and limitless ambition, and his primary desire is for self-preservation; he is shortsighted, judging most commonly by the immediacy of reward rather than the remote consequences of his actions; he is imitative, inclined to follow the example of authority figures; and he is inflexible, so that behavior patterns established through imitation can be changed only to a limited extent.

Given these traits, the outlook for social cooperation may appear dim, but this is not so: men's desire for self-preservation and their very shortsightedness make them peculiarly susceptible to manipulation by civic leaders, and as stated above, their imitativeness predisposes them to accept the conditioning provided by leadership and organization. Furthermore, under conditions of necessity, when their lives are threatened by a hostile physical environment or by an act of aggression, men's desire for self-preservation moves them to act cooperatively and even virtuously: they prove to be industrious, courageous, and self-denying. Even after an immediate threat to survival has been overcome, social virtues can be maintained by astute leadership and rational social organization. In other words, Machiavelli differentiated between an original (evil) and a second (socially benevolent) nature, between natural and socially acquired characteristics.

Man's essentially evil nature, then, is raw material that may be molded or conditioned by leadership and organization; although, to be sure, the original nature of the material limits its malleability. Man is capable of socialization, and more or less desirable characteristics can be imprinted on his original nature by education, in the sense of conditioning. Civil society is the great school of mankind. Human behavior can be vitally affected by the structure of the social environment, by the socially established ends that canalize human desire. All men are to some extent creatures of convention rather than merely natural men; indeed, neither an absolutely natural nor an absolutely conventional man can exist, any more than either an absolutely evil or an absolutely good man is possible. All men fall somewhere along a scale between these extremes. It seemed plausible to Machiavelli that good and evil are roughly in equilibrium in the

world, although their distribution may vary from age to age, each quality being in some periods concentrated in particular societies, and in other periods dispersed.

Values. The supreme end of politics, in Machiavelli's view, is the public utility, the security and well-being of the community rather than the moral goal imputed to politics by previous thinkers. When he assessed the validity of political precepts by examining the consequences of particular political acts, he treated moral acts like any other kind, from a strictly instrumental point of view. The social and political consequences of acts always interested him more than the moral intent of the actors, and he argued that in human affairs the consequences of acts are bound to be both good and evil. Basically, he was not concerned with the problems of moral philosophy, and he accepted the fact that a life of action is necessarily one of moral dilemma and paradox. Perhaps Machiavelli's one important moral insight, never explicitly articulated, is that the very conditions of personal morality are dependent upon the security afforded by the immorality of the state.

This does not mean that Machiavelli condoned violations of personal morality or that he was himself immoral. He did distinguish between moral and immoral acts in the conventional sense. He never suggested that some people are innately superior to others, thereby having a right to dominate and enslave. He was usually careful to affirm that the common good upon occasion excuses rather than justifies immoral means. Violation of the standards of personal morality is excusable only when necessary for the public utility. Statesmen must know how to act iniquitously for the sake of the common good; but violence, cruelty, and deception should never become ends in themselves, and they should always be rationally controlled.

While Machiavelli himself was not above moral reproach, he was born and died a Christian and was neither depraved nor unprincipled. His attacks on the church were anticlerical rather than anti-religious, being directed against the scandalous lives of the popes and their political activities. He did compare contemporary Christianity unfavorably with the paganism of the ancients, but he criticized Christianity primarily because it had become the means to socially undesirable ends—the subjection of the many to an avaricious minority—and called for a return to some kind of original creed. While he dwelt upon the socially pragmatic value of religion he did not view it from this standpoint alone.

The highest end to be pursued by man, according

to Machiavelli, is glory. Glory is conferred by acts that are remembered and cherished by mankind. The brief but glorious life of an individual or commonwealth is worth far more to Machiavelli than a lengthy mediocre existence. Mere success or reputation arising from great power or wealth has far less value than true glory. The greatest glory is to be won (in order of decreasing importance) by founding religions, by establishing commonwealths, by commanding armies, and by creating literature.

True glory depends upon the *virtù* of an individual or a people. Machiavelli's term is ambiguous, but what he seems most often to have had in mind is the pattern of conduct of the soldier in battle who displays foresight, self-discipline, constancy, determination, purposefulness, decisiveness, bravery, boldness, and vigor. War is only the archetypal struggle between *virtù* (the manly) and *fortuna* (the changeable, unpredictable, and capricious), for in fact all of life is such a contest. Rational control over the physical and social environments, so essential for human survival and well-being, depends upon the opposition of *virtù* to *fortuna*. By virtuous action men can control at least some part of their lives and limit the whims of chance.

Machiavelli again studied history to discover the conditions that produced the greatest possible amount of *virtù* in a commonwealth and the consequent achievement of glory. He decided that the most virtuous leaders and peoples were those of classical antiquity, particularly of republican Rome. The *virtù* of a people, he believed, depends entirely on education, while that of a prince or leader tends to be inborn but shaped by education. A republicanism in which liberty flourishes, defended by a citizens' army, is the atmosphere most conducive to the exercise of *virtù*; under these conditions political power will be the greatest and most durable, and the political order will be the most stable. The basic elements in Machiavelli's conception of political success, then, are glory, *virtù*, and liberty. Machiavelli lamented the decline of *virtù* in his own age; he condemned its luxurious, commercial life and directed his efforts to the problem of restoring the conditions of glory.

Conflict and corruption. Conflict is a vital concept in Machiavelli's political thought. He accepted conflict as a universal and permanent condition of society, stemming from human nature. The traditional classical and medieval view had been that social conflict is not a natural condition, and many classical and medieval thinkers had tried to design a type of social organization that would eliminate contention. The conception of social conflict as unnatural ran parallel to the Aristotelian concept that

matter at rest is more natural than matter in motion. Machiavelli abandoned the former of these ancient modes of thought with his notion of the naturalness of social conflict, although the latter was not discarded until the next century with Galileo's revolutionary insight that the natural state of matter is motion.

The basic manifestation of social conflict, according to Machiavelli, is the perennial struggle between the common people and the great and powerful. While this is clearly a notion of class struggle involving economic factors, Machiavelli's explanation of the struggle is not couched in economic terms. The primary cause of domestic strife and of war between states is, as he saw it, a lust for power and domination. Within any state, the overwhelming majority seek security for their persons and possessions, while a handful, either a hereditary aristocracy or a commercial oligarchy, desire to dominate the masses.

Inspired by Polybius, Machiavelli believed that such conflict is not only natural but that it may be turned to socially useful ends. Virtuous commonwealths exhibit this kind of conflict no less than do corrupt ones. The difference lies not in the presence of conflict in the one and the absence in the other, or even in the degree of conflict, but in the quality of conflict in each.

Conflict in a virtuous commonwealth takes place within certain bounds: it is limited by a patriotic dedication to the common good that supersedes narrow self-interest, by a willingness to respect law and authority, and by an aversion to the use of violence and nonlegal activity. Republican Rome, Machiavelli's ideal of the virtuous commonwealth as described in the *Discourses*, exemplified this kind of limited conflict in that the struggle between patricians and plebeians was institutionalized through the Senate and the popular assemblies with their tribunes. The very strength and unity of the republic together with the citizens' liberties depended upon the continued contest.

By contrast, Florence, as analyzed in the *History of Florence*, is Machiavelli's prototype of the corrupt state. In such a state, society becomes atomized; each man is for himself. Religious sentiment declines, and with it civic honesty, the spirit of civic duty, and respect for authority. Factionalism and conspiracy are rife, and government is the successive captive of the most powerful cliques. *Virtù* decays; avarice proliferates; indolence, luxury, and economic inequalities rend the social fabric. Corruption is likely to develop in an overly successful society that knows peace and prosperity for a lengthy period. With the lack of challenge to sur-

vive, with well-being and leisure, men turn to private advantage; laws are no longer vigorously observed and enforced or adjusted to compensate for new conditions. Prevention of corruption requires a return to first principles, a periodic renovation of the civic order. Even the greatest vigilance and most prudent statesmanship, however, will not stem the tide of decay forever. Change is the way of all things, and the best-ordered commonwealths—for example, Rome and Sparta—are bound to decline.

Government and politics. The most important contrivance at man's command for containing and canalizing man's egoistic nature toward socially desirable ends is, according to Machiavelli, the state. By means of the state man can create the conditions for security and well-being.

Although Machiavelli frequently used medical imagery to describe the state, his conception of it actually resembles a mechanism more than an organism. The state has no higher end or spiritual purpose, nor does it have a life or personality apart from the people who constitute it. What has come to be called "reason of state," an expression Machiavelli himself never employed, is the calculated and prudent policy of statesmen to advance the secular aims of the governed, not a superrationality.

In *The Prince* and the *Discourses* Machiavelli presented a twofold classification of states based on the number who rule—the polar types being monarchies and republics. Monarchies may be limited (France), despotic (Turkey), or tyrannical (Syracuse); republics may be mass (Athens) or balanced (Rome). Of the balanced republics, in turn, two principal types exist—aristocratic (Venice) and democratic (Rome). On the basis of the Florentine experience Machiavelli distinguished two unstable forms intermediate between monarchies and republics, which might best be called oligarchy and plebiscitary monarchy. Machiavelli also classified states in other respects: according to the way power is acquired; according to their tendencies to expansion (Rome) or preservation (Sparta), to corruption (Florence) or *virtù* (Roman Republic); and according to whether the constitution originates with a single lawgiver (Sparta) or develops over time and with experience (Rome).

Machiavelli had, of course, elaborate prescriptions for successful government. Good government rests upon the foundation of a strong military establishment for protection against the external enemy. The life, property, family, and honor of each citizen must be safeguarded against interference from other citizens. General economic prosperity should be encouraged, individual economic aggrandize-

ment prevented, and luxury strictly regulated. Adequate recognition must be given to the meritorious among the citizens, and advancement in the service of the state should be open to those who seek honor and glory. The best government draws upon and utilizes the skills of the governed, and the best state is one in which rank corresponds to ability.

These ends can be realized most fully in a republic patterned after the Roman one, which had a mixed constitution and such institutions as dictatorship in times of emergency, censorship, public accusations, popular assemblies, sumptuary laws, and a citizens' army. Republics, however, cannot be established everywhere; the form of the state should be suited to the conditions of a particular society. Moreover, the successful founding of any commonwealth depends on the presence of a single individual of the greatest *virtù* and prudence.

Any well-ordered state is, according to Machiavelli, a rational organization in which citizens know with a high degree of certainty the legal consequences of their actions, i.e., what they can and cannot do with impunity. Hence, central to Machiavelli's proposals for successful government is a rational system of law that will eliminate arbitrary rule by guaranteeing legal equality, by providing regularized procedures for the redress of grievances, by prohibiting retroactive laws, and by executing all laws vigorously and efficiently. Civil law should establish a state religion for the inculcation and maintenance of civic virtue. Law should also institute a citizens' army that will have a genuine stake in the common good and that will serve as a prime means of civic education, instilling citizens with a respect for authority, patriotism, and martial virtues.

Machiavelli's description of the model army in *The Art of War* gives a clearer picture of his concept of a rational society than does the *Discourses*. Since he viewed domestic politics as a kind of warfare and dealt with political matters as a general might deal with the problem of defeating an enemy, it is not surprising that he wrote about politics as classical military theorists wrote about war. Military stratagems are translated into political maxims of the same calculating objectivity, and a rationally organized and commanded army serves as a model of a rational social organization.

Most political situations, Machiavelli believed, are conspiratorial or counterconspiratorial, and conspiracy is primarily of a military character. The political art is akin to the military art with its premium upon secrecy, planning and preparedness, estimation of factors, flexibility, rapidity and decisiveness of execution, surprise, and deception.

These qualities characterize the conspiratorial methods necessary for founding or radically reforming a state and the counterconspiratorial methods required for maintaining a state (since conspiracy must be prevented by avoiding the hatred and contempt of the governed). Prior to Machiavelli, only military theorists had dealt in detail with the problems of conspiracy; in the *Discourses* (see III, vi), he formulated the West's first general theory of political conspiracy.

Not only did Machiavelli liken political situations to military ones and the art of politics to the military art, but he also considered political and military leadership to be similar. Political leadership resembles the creative activity of the general who organizes, disciplines, trains, and leads an army to victory. That *virtù* is the cardinal quality of political leadership as well as of successful generalship is significant. The political virtuoso is rational, calculating, and eminently self-controlled, plays many roles with aplomb, and is prudent enough to identify his own interest with the well-being of those he seeks to manage. Machiavelli's heroes are the ancient founders and the soldier-statesmen of the Roman Republic. He particularly admired the moderate, liberal-minded, and humane military genius Scipio Africanus Major.

Good internal government and successful foreign policy are carried on essentially in the same way. A state's foreign policy is advanced either by diplomacy or war. The familiar roster of necessary qualities is attached to skillful diplomacy—foresight, initiative, decisiveness, flexibility, and deception. Negotiation is the technique of the ambassador, who must be ready to persuade, temporize, or intimidate, as occasion demands. If negotiation fails, war may well be unavoidable. Careful military preparations must be made in peacetime because sooner or later war is inevitable, given man's nature. Machiavelli preferred a war with limited objectives and gains to total war.

Significance and influence. Although few would deny Machiavelli a foremost place among Western political thinkers, his reputation, all too often based on *The Prince* alone, has long rested on his description of the stratagems by which political power can be seized and conserved without regard for moral ends. Consequently, for centuries he has been vilified as devil's disciple and despots' tutor. More favorable appraisals have appeared in recent years: he is being discovered as the first political scientist, the first modern political theorist, or the first liberal. But these positive labels again contain only half-truths. One does find in Machiavelli's

thought harbingers of science, modernity, and liberalism. Yet it must not be forgotten that he had one foot firmly planted in the classical world, and this classical aspect of his work has had a considerable influence. The seventeenth-century English classical republicans—Harrington, Neville, and Sidney—found in Machiavelli theories of limited republican government and of a citizens' militia, and bequeathed them to the American constitutional fathers. Montesquieu came upon the Machiavelli of the *Discourses* in England, and his imprint is seen throughout the *Considérations sur les causes de la grandeur des Romains et de leur décadence* and also in *L'esprit des lois*, which in turn fired the radical Rousseau, the conservative Burke, and the liberal Tocqueville. Bodin, Hobbes, Spinoza, and Hegel all recognized Machiavelli's genius.

Machiavelli has also been vitally important as a military thinker. Because of his revival in *The Art of War* of the classical stress upon military training, discipline, and organization, he is unquestionably the father of modern military science, who directly or indirectly influenced practitioners and theorists from Maurice of Nassau to Clausewitz.

Today, Machiavelli is of importance as a forerunner of the rationalism of the Enlightenment. Notwithstanding his pessimism about human nature and cynicism about human behavior, he was not without hope. He never lost his vision of a good society and his faith that men could in part shape their destinies. Relevant to the social scientific concerns of our own time are his views on the integrative function of conflict, the instrumental value of law and ideology in shaping society, the role of conspiracy, and the political craft in general. A careful study of his military image of politics may help us to perceive more readily the inadequacy of our own comparable image of the political.

MACHINES, POLITICAL

See POLITICAL MACHINES.

Charles Howard McIlwain, political scientist and historian, was born in Saltsburg, Pennsylvania, in 1871. He received a B.A. degree from Princeton in 1894. Three years later he was admitted to the Pennsylvania bar, but shortly thereafter he accepted a post as teacher of Latin and history in a private school. His knowledge and interest in the fields of Latin, history, and law, which later found expression in his writings on English constitutional development and ancient and medieval political thought, were sharpened and refined during his study for the doctorate at Harvard from 1901 to 1903. In 1911 McIlwain was appointed assistant professor of history and government at Harvard and was promoted to a full professorship only five years later, which was quite extraordinary at the time. In 1927 he was named Eaton professor of the science of government, and he held this chair until his retirement in 1946. During an active teaching career which spanned almost half a century, he lectured at numerous universities, including Oxford. In 1936 he was elected president of the American Historical Association.

McIlwain was profoundly disturbed by the divorce of political science and history. The disciplines were brought together, especially at Harvard, through the force and originality of McIlwain's scholarship. The dominance of political theory, and its historical orientation, in the Harvard department of government is in large measure a legacy from McIlwain. His influence was strongly felt by scholars of his own day—Edward Corwin and George Sabine, to name but two—and the work of more recent theorists, such as Louis Hartz and Leonard Levy, reflects the continuing impact of McIlwain's approach to the study of political thought.

Historical roots of judicial activism. Avoiding the pitfall of reading the present into the past, McIlwain justly prided himself on his ability to interpret medieval writers such as Henry de Bracton and John Fortescue in terms of their own thinking and experience. His insight into juristic thought in England during the Middle Ages greatly contributed not only to a general understanding of the period but also to a clarification of political concepts such as constitutionalism and sovereignty. The unique and phenomenal discretionary power enjoyed by the American judiciary cannot be explained in the absence of an understanding of its historical roots in English jurisprudence. Addressing himself to this problem, McIlwain argued in *The High Court of Parliament* (1910) that medi-

eval English courts exercised similar powers. He hammered home the point that medieval judicial activism was due to a *fusion*, not a *division*, of governmental powers. It is therefore a misconception to regard the High Court of Parliament as a court of justice which, in addition to its judicial function, exercised legislative powers. The distinction between legislation and adjudication was simply not recognized, thereby allowing the lower courts, as well as Parliament, to exercise both types of powers.

The fusion of powers in governmental institutions spawned not only judicial activism but also what might well be considered its natural outgrowth, judicial review. It is only within the context of McIlwain's interpretation of the character of governmental powers in seventeenth-century England that Sir Edward Coke's famous statement that "in many cases the common law will controul acts of Parliament" ([1610] 1826, p. 375) is reconcilable with his earlier declarations that Parliament's power is absolute (in [1644] 1817, pp. 28-36). The apparent paradox vanishes when one realizes that Coke was not invoking judicial authority against legislative sovereignty, but holding that common law, as higher law, is binding upon the ordinary courts and the High Court of Parliament alike.

Constitutionalism. The crux of McIlwain's concern was the true meaning of constitutionalism. Throughout his writings he championed the principles of medieval constitutionalism, perhaps most effectively in a thin volume which has become a classic, *Constitutionalism: Ancient and Modern* (1940). He defined constitutional government as government limited by law. It embodies the basic distinction, so clearly drawn by Bracton, between *gubernaculum* and *jurisdictio*, between discretion and law. The same concept was echoed by Coke in his famous Case of Proclamations. "It is a grand prerogative of the King," Coke declared, "to make proclamation . . . [yet] the King hath no prerogative but that which the law of the land allows him" ([1656] 1826, p. 299). In a word, within the bounds of higher law, the king is supreme. Bodin, too, developed views of sovereignty that recognized both the absolute power of the sovereign to make ordinary laws and the limitation of the sovereign by fundamental law; McIlwain therefore regarded Bodin as a constitutionalist [see BODIN].

Against this concept, McIlwain critically posed the more modern view of constitutionalism, that is, that constitutional government must be founded upon a division of powers which effectively restrains governmental action. This view—which is,

in McIlwain's opinion, historically unsound—obscures the distinction between control and limitation. Constitutional government must be strengthened to survive in the modern world, not enfeebled by checks and balances which dissipate its powers and render it ineffectual. While McIlwain believed that responsible and effective constitutional government necessitates the removal of balances, he emphasized that the limits beyond which no government can legally go must be strengthened. In a vein strikingly similar to the legal absolutists' position in the United States today, McIlwain declared, "I frankly want to rely on the earlier, the sounder, yes the medieval principle, that there are some individual rights that even a people's government can never touch" (1917-1937, p. 263). He placed complete reliance upon the judiciary to hold the line.

Viewed from a functional approach, McIlwain's juristic concept of constitutionalism is subject to major criticism. Intent upon demonstrating that the medieval *idea* of supreme, limited government embodied the true principle of constitutionalism, McIlwain was little concerned with the problem of the power relations necessary *actually* to limit government. Clearly, a balance of power within government may hamper governmental responsibility and effectiveness; however, it appears to be equally true that government cannot be effectively limited if it does not reflect a division of power among groups and classes within the community. Indeed, during the Middle Ages constitutionalism was actually operative only in those periods when the king was restrained by the power of the ecclesiastical authorities and the feudal landowners.

Convinced of the merits of the medieval distinction between control and limitation of government, McIlwain was naturally critical of the doctrine of separation of powers and the doctrine of checks and balances, both of which clearly violate this distinction. His argument would have been on firmer ground if he had not ignored the important question of whether government can be effectively limited in the absence of institutionalized controls.

MACIVER, ROBERT M.

Sociologist, political theorist, philosopher, university administrator, and humanist, Robert Morrison MacIver was born in Stornoway, Scotland, in 1882. He will be remembered in the history of Western thought for having set forth systematically the fundamental moral, sociological, and philosophical principles of democratic institutions and processes.

Although he sought answers to the perennial theoretical problems of social, political, and moral philosophy that seem to defy ultimate solution, MacIver did not eschew concern for the mitigation of immediate social problems. He attempted to demonstrate by precept that sociological insights can be practicably applied to such pressing problems as labor relations, economic reconstruction, internationalism and peace, intergroup conflicts, religion, academic freedom, social work, juvenile delinquency, and effective utilization of manpower resources. He was vice-chairman of the Canadian War Labor Board in World War I and director of the City of New York Juvenile Delinquency Evaluation Project from 1956 to 1961, and he contributed effectively to the leadership of the Social Science Research Council, the Russell Sage Foundation, and the National Manpower Council.

MacIver's very important contribution to political theory is his view of the state as an agency of human purpose. The state, he argued, is an association established by the community for the

regulation of the external conditions of the social order. It is thus an instrumentality within a more inclusive unity. Its essential tasks are to establish order and to respect personality, but it is a creature of society and is bound by the value systems that men live by and for. MacIver revealed the intimate relations between political structures and processes, on the one hand, and human values, on the other.

MacIver's contributions to sociology may be viewed as fourfold. First, he systematically developed and fruitfully exploited an impressive network of fundamental sociological concepts. Second, he helped stem the tide of excessive positivism and raw empiricism in American sociology, especially through his insistence on theory as a methodological tool. The progress of science, he suggested, is the progress of thought. Every scholar should be at the same time a specialist in his own field and a thinker about a larger one (1960, p. 30). Third, he reaffirmed the view of man as a creative human being with subjective hopes, feelings, aspirations, motives, ideals, and values. Life, he insisted, is expansively creative. Finally, he demonstrated that sociological writing can be clear, artistic, and literate. To an area of confusion and literary and intellectual chaos, MacIver brought both clarity of thought and felicity of expression.

Especially important in MacIver's sociological system are his classification of social interests, the distinction between community and association, the concept of social evolution, the harmony theory of the relation between society and individuality, and the differentiation between the institutions concerned with means (civilization) and the world of ends (culture).

The classification of social interests, particularly the distinction between like and common interests, has proved of immense value in clarifying the nature of interindividual relationships, the bases of group organization, and the nature of the social bond. The distinction between community as the matrix of social organization and associations as specific organizations which grow and develop within that matrix is the keystone of MacIver's political doctrines. To sociologists the distinction has proved significant in permitting a more precise definition of the problem of social solidarity and in providing a framework for a deeper understanding of the nature of a pluralistic or multi-group society.

MacIver's reaffirmation of the validity of the concept of social evolution, in the face of the bitter attacks upon it by anthropologists such as Goldenweiser, anticipated by many years the resurgence

of interest in and the defense of the concept by Julian Steward and other American anthropologists, as well as by sociologists such as Talcott Parsons (1964), Robert Bellah (1964), S. N. Eisenstadt (1964). Numerous insights have stemmed from MacIver's tracing of a pattern of social change from the primitive type of functionally undifferentiated society, wherein life is of a communal nature, to the more evolved, functionally diverse, and institutionally and associationally differentiated social entity, wherein the basis of individual relationships is less communal and more associational and wherein personality becomes more developed and more expansive.

Important, too, is MacIver's resolution of the timeworn controversy of the relationship between the individual and society. Rejecting both social contract theories and organismic theories, he stressed the fundamental harmony between individuality and society, recognizing, at the same time, that this harmony is far from perfect. Sociality and individuality, he asserted in one of his most successful formulations, develop *pari passu*.

Also significant is the distinction between the world of means (civilization) and the world of ends (culture). The terms are unfortunate because of the more traditional connotations of "civilization" and "culture," but the emphasis on the difference between means and ends provides numerous analytical insights into the processes of social change and a better understanding of the functions of various social institutions. It indicates the areas of social life to which one may properly apply the concept of progress.

MacIver was an inspiring teacher. He had an impact on students at Aberdeen University, the University of Toronto, Barnard College, and Columbia University. At Columbia he held for more than twenty years the chair of Lieber professor of political philosophy and sociology. He served as president of the New School for Social Research in 1963/1964. He received advanced degrees from the universities of Edinburgh and Oxford and numerous honorary degrees.

In his Kurt Lewin memorial award address of 1961, MacIver stated: "In every area of scientific research we have often to depend on degrees of probability, on approximations, on indirect approaches, and such procedures can yield results of considerable importance. There are many ranges between certitude and ignorance, and nearly all we know about human beings and human activities lie within these ranges" (1962a, pp. 89-90). He has not been afraid to face "the paradox of knowledge," namely, that "the only things we know as im-

mutable truths are the things we do not understand," while "the only things we understand are mutable and never fully known" (1938, p. 124).

MACKINDER, HALFORD

Sir Halford John Mackinder (1861-1947) was both an academic geographer and a practicing politician. After reading physical science and modern history at Oxford, he served that university's pioneer extension scheme for adult education. He was deeply convinced of the value of this missionary effort to spread knowledge more widely in England. He lectured up and down the country between 1885 and 1893 on what he called "the new geography." He was a natural orator, and he preached his geographical gospel with zeal and fervor.

At that time the subject of geography did not occupy a high place in British or American education; it had little or no prestige in the universities. The fame of Mackinder's Oxford extension lectures reached the Royal Geographical Society of London. In January 1887 he was invited to lecture to the society on the scope and methods of geography. In the discussion after the lecture he defined geography as "the science of distribution, the science, that is, which traces the arrangement of things in general on the earth's surface" (1887, p. 160) and urged that physical and political

geography be combined. An examination of the lecture shows that many notions that are now commonplace in geographical teaching were first enunciated by Mackinder.

Mackinder had a special mission for geography that still has considerable importance: in the 1887 lecture he said that "one of the greatest of all gaps lies between the natural sciences and the study of humanity. It is the duty of the geographer to build one bridge over an abyss which in the opinion of many is upsetting the equilibrium of our culture" (p. 145). In the same year that he gave this lecture Mackinder was appointed to a readership in geography at Oxford; he claimed that he was the first Oxford reader in geography since Hakluyt, the Elizabethan. As a result of Mackinder's efforts, the school of geography was established at Oxford in 1899; this was the first British university department of geography.

The idea of the region was an implicit part of Mackinder's argument for geography as an academic discipline. At Oxford one of his regular annual courses was always concerned with the analysis of a particular region. His *Britain and the British Seas* (1902) is one of the few classics of modern geographical literature. This book was the first of a series planned by Mackinder to present "a picture of the physical features and condition of a great natural region, and to trace their influence upon human societies" (1902, p. 7). By their efforts at Oxford both Mackinder and his successor, A. J. Herbertson, placed the study of regions in the forefront of geographical work. Mackinder also taught that geography is a unity which should not be split into fragments. These ideas about the unity of geography as a subject and the necessity for basing it on integrated studies of regions are the foundations upon which modern British academic geography has been built.

In January 1904 Mackinder read a paper entitled "The Geographical Pivot of History" to the Royal Geographical Society. He was then still teaching at Oxford but had just been elected director of the London School of Economics. Mackinder described a central part of Eurasia as "the pivot area," a term he later changed to "heartland." In his lecture he laid down two principles. The first was that since the modern improvement of steam navigation, the world had become one and, in so doing, had also become one closed political system. The second and main point of his argument concerned the importance to the world of the modern expansion of Russia. He asserted that "the pivot region of the world's politics" is

"that area of Euro-Asia which is inaccessible to ships," and is controlled by Russia (1904, p. 434). If the world is regarded as a unit, he argued, combinations of power "are likely to rotate round the pivot state, which is always likely to be great, but with limited mobility as compared with the surrounding marginal and insular powers" (pp. 436-437). In the discussion after the lecture Mackinder bluntly asserted that the development for the first time in recorded history of a great stationary population in the steppes constituted a revolution in the world (p. 442). In 1919 Mackinder expanded his paper into a book, *Democratic Ideals and Reality*, which was described by J. Russell Smith as "a tract addressed to the Peace Conference at Versailles" (1945, p. 148). It contains the famous warning: "When our Statesmen [at Versailles] are in conversation with the defeated enemy, some airy cherub should whisper to them from time to time saying: 'Who rules East Europe commands the Heartland: Who rules the Heartland commands the World-Island: Who rules the World-Island commands the World'" ([1919] 1942, p. 150).

Between the two world wars Mackinder's theory of the heartland received little attention in the English-speaking world; but it was closely examined in Germany, where it became a basic idea among the students of geopolitics (*Zeitschrift für Geopolitik*, *passim*). General Karl Haushofer (1937) described Mackinder's 1904 paper as the greatest of all geographical world views. During World War II, Mackinder's idea of the heartland received considerable attention in both Britain and America. In 1943 Mackinder, then 82 years of age, restated his heartland theory, with modifications, in an article in *Foreign Affairs*. He believed that his concept of the heartland was even more valid than it had been forty years earlier, and he boldly asserted that "... if the Soviet Union emerges from this war as conqueror of Germany, she must rank as the greatest land Power on the Globe. Moreover, she will be the Power in the strategically strongest defensive position. The Heartland is the greatest natural fortress on earth. For the first time in history it is manned by a garrison sufficient both in number and quality" (1943, p. 601).

Mackinder's writings on land power can be compared with those of Mahan on the influence of sea power [see the biography of MAHAN]. It has been suggested that modern air power destroyed the validity of the arguments of both Mahan and Mackinder. But Mackinder in 1919, and again in 1943, used the coming of air power to support his

older thesis. He also stated his conviction that the conquest of the air gave the world's unity a new significance for all mankind. W. Gordon East, in a reasoned commentary of Mackinder's theories in the light of more recent events, similarly insisted that Mackinder's "geopolitical thinking is still relevant to the task of winning the peace" (1950, p. 93).

Mackinder's interest in politics led him to become a practicing politician, and he was a member of Parliament from 1910 to 1922. He also served as British high commissioner for South Russia in 1919-1920. But his achievements in politics are not as memorable as his pioneer research in the field of applied geography. He created modern British geography as a university subject. He can be regarded as a founder of several of its branches, especially that of political geography, but he steadfastly believed in the unity of the subject as a whole. He wanted geography to enlighten the practical affairs of daily life. In his own words, "geography must underlie the strategy of peace if you would not have it subserve the strategy of war" (1931, p. 335).

McLENNAN, JOHN FERGUSON

John Ferguson McLennan (1827-1881), Scottish lawyer and theorist of social evolution, was born in Inverness and died in Hayes Common in Kent. He was educated at King's College, Aberdeen, graduating with distinction in 1849. He went on to Cambridge, where he stayed until 1855 without taking a degree. In 1857 he was called to the Scottish bar, and in 1871 he was made parliamentary draughtsman for Scotland. In 1874 Aberdeen University conferred on him an honorary doctor of laws degree. McLennan's later life was marred by continual ill health, and much of his work was published posthumously, edited first by his brother Donald and then by W. Robertson Smith. After these two had died, the remaining manuscripts were edited by McLennan's widow, Eleanora, and a friend, Arthur Platt.

McLennan's legal studies led him to an interest in "symbols," i.e., survivals in contemporary cultures of previous legal and customary behavior. He noted, for example, that even as late as the nineteenth century Scottish law was replete with feudal concepts. Another of the striking survivals that McLennan described and elaborated upon was the custom of simulated bride capture: as it occurred in ancient Rome, he suggested, it was a symbol of the actual practice of earlier times.

His attempt to account for such survivals led to a theory of the evolution of social forms. In this context he proposed a sequence of familial development in which matrilineal kinship preceded patrilineal. He suggested this sequence independently of J. J. Bachofen, who first proposed it. He defended his theories, sometimes acrimoniously, against the views of Maine, Morgan, Lubbock, Spencer, and even of Mr. Gladstone. Because McLennan saw contemporary primitive peoples as representing various stages of arrested social development, he believed that historical reconstruction consists in noting trait survivals and discovering functional explanations for them. Thus, when customs appeared to be nonfunctional, he attempted to deduce the earlier context in which they had arisen and in which they *had* been functional. When, for example, the levirate—wherein a man

inherits his brother's widow—was found to coexist with polyandry in any society, one could conclude that polyandry was a necessary precondition for the levirate. McLennan developed his entire scheme of social evolution on this principle.

McLennan is chiefly remembered for his invention of the terms *exogamy* and *endogamy*, and for his analysis of totemism. These concepts emerged from his general scheme of evolution, which ran as follows: Originally, tribes were promiscuous, children being affiliated with the social group rather than with their biological parents. Harsh conditions of existence led to female infanticide. Because of the resulting sex imbalance, and also because these early tribes were always warring, capture came to be the prevailing method of obtaining wives. The corollary of bride capture was exogamy, which obliged men to seek marriage partners outside of their own social group. Such marriages were of the archaic polyandrous type, where no regulated relationship existed among the male partners of one woman. Since paternity could not be biologically determined, kinship was traced through females only.

According to McLennan's scheme, the capture of foreign women and matrilineal kinship furthered the recognition of subtribal divisions. These new social units continued to be exogamous, while for the larger tribal group, endogamy became possible. It should be noted that McLennan never clarified the identity of the social units involved; Morgan, in rebuttal of McLennan, insisted that the subtribal units were clans. Nevertheless, McLennan's conception of this early stage of polyandry did take cognizance of what later ethnologists have called local exogamy and the rules of residence attending upon marriage.

As the archaic form of polyandry was transformed into fraternal polyandry, the levirate became common practice. Kinship could then be established through males, and the way was paved for monogamy and polygyny. The thread of functional reasoning runs through all of this deductive reconstruction, but the ethnographic information on which McLennan based his evolutionary scheme was inadequate and resulted, therefore, in incorrect deductions. Moreover, the assumption of universal stages of social evolution based on no criteria other than kinship rendered his arguments circular. It is fair to say that McLennan was not unique in his faults, which stemmed not so much from his own inadequacies as from the currently accepted mode of evolutionary analysis. His critics were guilty of the same errors.

Of his debates with these critics, the only one

that retains its significance is that with Morgan, on the meaning of kinship terms. McLennan (1876) argued—against the views of Morgan in his *Systems of Consanguinity and Affinity of the Human Family* (1871)—that kinship terms are not indicative of consanguineous relationships but express “degrees of respect” based on “age and station.” This point—that the terms refer to statuses and not to blood relationships—is now accepted; but anthropologists are still divided into those who follow Morgan and attach great significance to terminology and those who, perhaps unwittingly, follow McLennan in thinking that its importance is overrated.

McLennan's ideas concerning totemism were also part of his parallelist emphasis. He saw the totemic symbols attached to kinship groups as survivals of an earlier, localized worship of fetishes, and the worship of animals, plants, and eventually, of anthropomorphic gods was seen in terms of survivals derived from totemism. Exogamy caused totemic identifications to be dispersed, because they were transmitted through the female line. According to McLennan, totems became gods—often associated with a particular locality—when patrilineal descent groups were formed. His idea of totemism as the most primitive form of religion had wide influence. It is echoed in the work of Freud and Durkheim, and it directly influenced the thinking of Frazer (1887), Jevons (1896), and Robertson Smith (1885; 1889). Robertson Smith, a close friend and collaborator, interpreted the religious and social evolution of the Semitic peoples in accordance with McLennan's theories. Tylor (1899) was one of the first of many to criticize McLennan's totemic theories of the origins of religion. He insisted that totemism is of “far greater importance in sociology than religion, connected as it is with the alliance between clans which ensues from the law of exogamy.” This, together with Tylor's opinion that totemism is an expression of man's tendency to classify the universe, represents the most influential modern view (see Lévi-Strauss 1962).

MADISON, JAMES

James Madison (1751-1836), fourth president of the United States, from 1809 to 1817, was the principal framer of the constitution of 1787. It was Madison who made the first preliminary move toward the drafting of the constitution by sponsoring the Annapolis Convention of 1786. The constitution embodied his conviction that liberty and the rights of property could best be harmonized and secured in a federal republic, with powers divided between subordinate states and a supreme federal government, each with internal checks and balances to prevent the rise of arbitrary power. According to Madison, republican government required that representatives be elected directly (or, perhaps, in one house, indirectly) by the great body of the people; otherwise the republic would degenerate into an aristocracy or an oligarchy. Government so organized, he believed (relying to some extent on Hume), would be progressively safer to liberty and property as the territorial area was enlarged, since diversity of regional interests and of population would prevent any national majority—whether moved by a common property interest, by political or religious passion, or swayed

by an ambitious leader—from gaining power and oppressing the minority. He believed that the acquisition and protection of property is the ruling force in political faction and that the need to protect liberty and restrain power is a pressing one. These concepts, which he presented to the Philadelphia Convention of 1787, persuaded delegates fearful of the excesses of democracy to place their trust in democratic self-government. His voluminous notes of debates furnish the principal record of the convention.

In Congress Madison introduced the first ten amendments to the constitution, designed to enlarge its libertarian provisions into a bill of rights. In presenting these amendments he placed heaviest emphasis on freedom of religion, speech, and press. The religious guarantee was based on his modification of the 1776 Virginia Declaration of Rights, which discarded "toleration" and affirmed absolute rights of conscience, and on his successful "Memorial and Remonstrance Against Religious Assessments" (1785) for support of teachers of religion; such assessments, he asserted, were tantamount to an establishment of religion. His expectation that "independent tribunals of justice" would form "an impenetrable bulwark" against every encroachment on constitutional liberties was dashed by the enactment and savage enforcement of the Sedition Act of 1798. Consequently he wrote the Virginia Resolutions of 1798, which asserted the right of the states, in case of a deliberate and dangerous violation of the federal compact, to interpose collectively "for arresting the progress of the evil." Widespread interpretation of this as an assertion of the right to nullify acts of Congress led to his "Report on the Resolutions" (1799-1800), likewise adopted by the Virginia legislature, which defined interposition as an exertion of influence within the terms of the constitution but denied interposition any judicial force. The "Report" was notable for its assertion that freedom of the press exempted the press from punishment for licentiousness and its denial that the federal government had power to punish crimes under the common law of England.

In the famous *Federalist* No. 10, Madison systematized his earlier discussions of political faction. By that term he did not refer to political parties of the modern type but to the united activities of a majority or minority of the people "actuated by some common impulse of passion, or of interest, adverse to the rights of other citizens, or to the permanent and aggregate interests of the community" (Hamilton, Madison & Jay [1787-1788] 1961, p. 57). The unsteadiness and injustice

of state governments, resulting from a factious spirit, had led to the breakdown of public trust and increasing alarm for private rights. The latent causes of faction, he believed, lie in the nature of man, especially men's varying capacities for acquiring property and its consequent unequal distribution. Liberty feeds faction, but limiting liberty is a greater evil than faction. The remedy, therefore, lies in controlling the effects of passion through checks and divisions of governments.

Madison had a deterministic view of human conduct and was essentially a pragmatist, committed to no particular school of political thought but intensely devoted to preserving the Union, maintaining a broadly based republican government, and protecting human rights. In the furtherance of national policy, his tendency was to rely upon coercive measures. In the first Congress, he sponsored a moderate protective tariff (though generally preferring free trade), advocated counter-discrimination against British navigation acts injurious to American shipping, and worked unofficially to help repel senatorial encroachments on the president's powers. Madison and Hamilton were equally committed to full payment of depreciated Revolutionary War claims, but Madison resisted Hamilton's policy of full payment to speculators who purchased claims, urging that a share should go to the original holders, mostly impoverished veterans. This initiated the political alignment that developed into Hamiltonian federalism and Jeffersonian democracy. Hamilton's sweeping interpretation of the power to spend for the general welfare likewise prevailed over Madison's attempt to limit spending to subjects covered by the other enumerated powers—a view which did not prevent him, as president, from inaugurating government distribution of smallpox vaccine.

Jay's 1794 treaty with England blocked Madison's counterdiscrimination policy, but maritime restrictions continued and the Napoleonic Wars provoked wholesale seizures of American ships by both belligerents. In striking contrast with President Jefferson's defensive shipping embargo, Madison in his first month as president made identical offers to England and France: that if the power addressed would cease its aggressions against American commerce, and the other continued them, he would ask Congress to declare war against the continuing offender. Without knowing of these offers, Congress in effect gave them legal force by the Macon Bill No. 2 of 1810, leading to the War of 1812 with England.

Except during his student days at Princeton and the major portion of his years in public office,

Madison spent his entire life on his extensive estate, Montpelier, in the Virginia Piedmont. He pioneered in modern scientific agriculture and warned of the future dangers from world-wide overpopulation and man's upsetting of the balance of nature. Although strongly opposed to slavery, he lived by its fruits. The apparent happiness of his slaves, he told Harriet Martineau, was an illusion, concealing the degradation inherent in the institution. Believing that white Americans would permanently deny rights to which freedmen were entitled, he advocated the freeing of all slaves through government purchase—to be financed by western land sales—and voluntary resettlement in Liberia and other separate communities. The final years of his life were devoted to his work as rector of the University of Virginia and to preparing polemical articles combating South Carolina's nullification doctrine.

MAGIC

The article under this heading discusses witchcraft and sorcery as well as magic. Related material will be found under POLLUTION; RITUAL; and in the articles mentioned in the guide to RELIGION. The biographies of DURKHEIM; FRAZER; KLUCKHOHN; MALINOWSKI; MAUSS; and NADEL should also be consulted.

The relation of magic to religion and to science provided fuel for early anthropological speculation. All students of primitive religion have had to face the question in some form or other. It has proved difficult to circumscribe the subject of magic with any degree of precision. If, as is often the case, the subjects of *mana*, taboo, totemism, and ritual are included, the discussion of magic easily dissolves into comparative religion.

In recent years, apart from a notable work on taboo (Steiner 1956), there has been a lack of interest in magic, although the work of Lévi-Strauss on primitive thought (1962; 1964) promises to revive discussion. In the past 30 years anthropologists have concentrated on describing and analyzing the moral and religious ideas and institutions of particular peoples in great detail. In these studies the great philosophical issues of magic, science, and religion, which exercised thinkers in the nineteenth and early twentieth centuries, have receded into the background. There has been great interest in specific institutions, such as sorcery and witchcraft, which may be regarded as the social dimensions of magic. Although theoretical formulations in these fields have not kept pace with the greatly increased area of knowledge, such contributions as those of Evans-Pritchard (1937), Kluckhohn (1944), and Nadel (1952) have had important repercussions.

In historical terms, there can be seen a development from attempts to single out isolated and exotic instances of belief or practice in order to buttress a highly abstract philosophical position (such as Frazer's work) to an effort to place all magical acts in their proper context within the totality of moral and religious ideas, institutions, and practices of a culture.

For nineteenth-century thinkers like Tylor (1871), McLennan (1865-1876), Spencer (1876-1896), and Lang (1901), the question of greatest interest was the origins of magic as related to the origins of religion. Their works were attempts to understand how early man was led in the direction of superstition by faulty observation and reasoning. This line of inquiry led to Lévy-Bruhl's famous work on primitive mentality (1910). Frazer (1890) was also working on evolutionary premises. Theories regarding the evolution of religion or science from magic are no longer in vogue, but Frazer's work will remain one of the most sustained efforts to penetrate the difficulties of the subject. Frazer regarded magic as an earlier, primitive form of both religion and science. He observed rightly that primitive practice is often based on excellent observation of natural phenomena and involves a theory of causality. He therefore felt that there was a basic similarity between magic and science. The only difference was that for a variety of reasons the mistaken assumptions and erroneous conclusions of magic were veiled from the observer and did not shake his beliefs.

The basic principles of magic, according to Frazer, were two: the law of similarity and the law of contagion. According to the first principle, like produces like, so that sticking pins into a doll is like sticking arrows into the enemy; and according to the law of contagion, prolonged or intimate contact produces identity, so that the enemy's nail parings and hair can be treated as if they represented him.

Evans-Pritchard (1933) has remarked that if Frazer had observed what the natives did rather than what they thought, he would have been less inclined to draw similarities between scientists and witch doctors. He would also have seen the difference between scientific methods and traditional arts.

While anthropologists were skeptical about the attempt to reduce the exuberant complexity of primitive ritual and magic to two principles of thought, the initial impact of Frazer's ideas was considerable, especially beyond the circles of academic anthropology. In retrospect, Frazer's work is generally regarded as having one crippling diffi-

culty: similar customs and practices from all cultures of the world were collected and examined under common labels. Since the labels and their relations exemplified Frazer's own thinking on the subject, the data merely filled the preconceived receptacles and did not add to the analysis of the phenomena in any one culture (Leach 1961).

Since Frazer, every major writer on primitive religion has struggled with "magic," and every major monograph has provided more material on this elusive subject. Durkheim (1912), for instance, distinguished magic and religion on the assumption that religion presupposed a church or a congregation, while the magician worked alone and merely had a *clientele*.

Malinowski wrote in a different vein. In his article "Magic, Science and Religion" (1925), he argued, in Frazerian terms, for the necessity of distinguishing among these fields, but on a non-evolutionary basis. Magic, he suggested, is related to anxiety. In ordinary, everyday economic pursuits there is no magic. But when the outcome of the enterprise is uncertain and there is danger involved, the native has recourse to magic. Moreover, magic is directed to specific ends and differs from religion in not being concerned with the worship of spiritual beings.

As Malinowski pointed out, the natives of the Trobriand Islands are perfectly able to distinguish the sphere of magic from that of technology. Thus, although every step of the cultivation process is marked by magical rites, there is no question of giving up one's own efforts to cultivate gardens and attempting to grow the food by magic alone. On the contrary, they know that even after having spent their best efforts on cultivation, some unpredictable act of nature may destroy their crops. Thus, argued Malinowski, the native has his "scientific technology" clearly distinguished from the sphere of magic. It is against the unpredictable that magic is utilized. Natives would consider it laughable to do otherwise.

This pragmatic point of view expressed by Malinowski has had many supporters. (We may observe also that the relation which he posits between anxiety and ritual harks back to psychoanalytic theory.) But the utilitarian basis of these theories has recently been severely questioned. It has become clear that the facts of ethnography do not fall into place as neatly as Malinowski had thought. Some features of magic, of Australian increase ceremonies, or of totemism don't make sense in simple utilitarian terms. Malinowski wrote, for instance, that "... food is the primary link between the primitive and providence. . . . The road from the wilderness to the savage's belly and conse-

quently to his mind is very short" ([1925] 1948, pp. 26-27). But in the magical repertoire of aboriginal Australians there are "increase ceremonies" for all kinds of nonutilitarian categories—for instance, mosquitoes—and simple pragmatic explanations for such complicated facts would be naive.

Malinowski had specifically dismissed the views of Mauss, who had argued (see Lévi-Strauss 1950) that magic is a special application of the forces of sacred powers, like *mana*, some conception of which is found in every society. For Mauss, *mana* was, in fact, a connection between religion and magic. Magic comes from religion into the realm of everyday life, where its end is action.

Malinowski, in denying the role of *mana*, attempted to place the emphasis again on pragmatic functions. He asked, "... what is *mana*, this impersonal force of magic supposed to dominate all forms of early belief? Is it a fundamental idea, an innate category of the primitive mind, or can it be explained by still simpler and more fundamental elements of human psychology . . . ?" These fundamental elements turn out to be merely "a blend of utilitarian anxiety about the most necessary objects of his surroundings. . . . With our knowledge of what could be called the totemic attitude of mind, primitive religion is seen to be nearer to reality and to the immediate practical life interests of the savage" ([1925] 1948, pp. 4-5).

Lévi-Strauss (1950) upholds Mauss and is concerned to redress the balance in favor of an argument that the inner logic of religious ideas is not utilitarian and that their logic has to be understood in their own terms. Features of primitive belief must be examined not by imputing our materialist viewpoint to the idealized native but in terms of the position of such ideas and symbols in the total tapestry of customary belief and practice. Thus, Lévi-Strauss agrees with Mauss and notes that the concept of *mana* is truly like a common denominator for concepts of the "sacred" and is, indeed, intimately related to magic. The conclusion here is that to understand magic, we must understand the refractions of the concept of the sacred in the culture.

Magic, then, is not a uniform class of practices and beliefs which can be immediately discerned in every society. On the contrary, it is best regarded as an aspect of religious belief and practice that takes its special force from the antecedent and deeply rooted recognition in many societies of supernatural or divine power. The place given to the practical use of such powers for everyday purposes such as healing or assuring luck and fertility—which in very general terms we may refer to as magic—differs from society to society.

Witchcraft and sorcery also involve the belief in supernatural powers, and sorcery in particular may be regarded as a specialized branch of offensive magic. What is said about magic and religion holds true for witchcraft and sorcery as well: it is imperative to place these beliefs and practices within the context of the total supernatural belief system of the culture in question. It will then be feasible to raise the question of whether there is logic in this madness and to what extent the different parts of the supernatural system show structure, division of labor, and specialization of function.

Sorcery and witchcraft

The terms "sorcery" and "witchcraft" refer to practices and supernatural beings which are part and parcel of the European Christian tradition. Their use in anthropology involves an essential widening of their meaning to cover a great many beliefs and practices from other cultures which have proved difficult to classify. The conceptual categories involved in such supernatural beings and practices are sometimes so unique to particular peoples that the translation of concepts from one cultural idiom into another becomes a difficulty of the first magnitude. Is "witchcraft" similar to the "evil eye"? Is a European witch the "same" as an Islamic djinn or a Hindu *yakṣa*? These questions about the similarities and differences between belief systems of different cultures remain largely unresolved.

With the above general reservations, it may be noted that in the area of witchcraft and sorcery, the empirical and theoretical distinctions made by Evans-Pritchard (1937) in his analysis of the ideas of the Azande have won general acceptance. The conceptual distinction made by the Azande has been observed in numerous other African cultures. The distinction turns on the nature of witches. According to Azande theories, "witches" are ordinary members of society who have inherited special supernatural powers to harm others and who may be completely unconscious of their evil potentialities. The Azande have consistent and developed physiological theories to explain just where in the human body such powers lie. They also have their special ways of consulting oracles to discover who among them carries the power, the reason for the attack, and how the danger is to be averted. Among the Azande these witches who are singled out by their fellow men are sharply distinguished from "sorcerers." Sorcerers are men who have learned the particular techniques of handling special substances and charms whereby they can affect others. While the witches' supernatural powers are innate

and unconscious, sorcery is an acquired technique and is conscious. In one case a person fully unconscious of his guilt may be publicly accused as a "witch" and by the use of oracles may be confirmed as such, whereas in the other case, at least in theory, there is a conscious agent responsible for certain incidents who may or may not be accused of evil intentions.

These distinctions have thrown light upon anthropological field information beyond the Azande material from which they were developed. Sorcery theory and practice are evidently very widespread on all continents; but witchcraft, with its direct accusations of certain individuals who may be totally unaware of what they are accused of, is a more remarkable and less widespread phenomenon. Apart from the celebrated medieval European and New England examples, cases of witchcraft accusation from parts of Middle America (Nash 1960) and central and east Africa also have been described. On the whole, the term "witchcraft," in the narrow sense, has not been used to describe related phenomena in the Near East and south Asia.

The above definitions make it possible to distinguish a gradation of witchcraft belief ranging from the fully developed dogmas that certain people become witches in some form (which may be embellished with detailed stories of their secret meetings and activities) to vague feelings that certain people might possess occult powers (such as the evil eye) to cause some harm, even though they may not be directly accused. The latter fear, in various degrees, is very widespread in the Mediterranean region as well as the Near East and south Asia, even though these powers are not usually described as "witchcraft."

It should be underlined that this distinction between sorcery and witchcraft lies entirely within the region of ideas and that there may be no "objective" basis to either set of beliefs. In other words, although it should be theoretically possible to observe the sorcerer at his work, and although external evidence could be produced in the form of magical substances, special bundles, and the like, it is also quite possible that while there may be widespread fear of sorcery, it may in fact never be practiced by anybody. In this sense, in the study of both sorcery and witchcraft we are almost entirely concerned with the analysis of supernatural beliefs.

Cultural and structural approaches

Although descriptive works of high quality are now numerous, little progress has been made by anthropologists into the systematic analysis of customary belief systems. The dilemma has remained: how far are belief systems to be related to and

analyzed in terms of the economic and social structures of the groups in question? Or if such systems are not directly related to economic and social structures, are there internal logical and categorical features which produce consistency and form in belief systems? The differences between these approaches have made themselves felt in the emphasis placed on the cultural or structural aspects of these phenomena.

Internal features of belief systems. The cultural approach to witchcraft and sorcery has underlined the consistency or logical closure of such systems: thus witchcraft and sorcery ideas are theories of causation concerning good and evil in human society. When a misfortune takes place, it can be explained by witchcraft or sorcery. This explanation in turn involves the necessity of discovering the agents of causation, i.e., those witches and sorcerers responsible. Thus, beginning with a theory of causation, one is led to techniques of divination. These, in turn, necessitate the development of the arts of healing and defense. Hence, ideas regarding witchcraft and sorcery become part of a coherent and consistent set of ideas regarding the nature of events in the world. Since these ideas have very wide ramifications and are inextricably related to the thought, language, and customary behavior of the societies in question, convictions regarding witches, sorcerers, and magic cannot be contradicted on simple rational or empirical grounds. They are rooted deep in the nature of social life.

There has been little analysis of the total "design" of supernatural belief systems, even though witnesses in the field have generally taken their coherence for granted. The "design" means here the characteristics, roles, rights, and obligations of supernatural beings, their organization and relations with each other and with human society at large. It also includes the methods whereby they may be approached, communicated with, appeased, angered, or utilized. It seems clear that all societies have a design of this nature whereby a division of labor between different sections of the supernatural is effected.

An example of the operation of such a system is to be seen among the Sinhalese villagers of Ceylon. In these communities the world of supernatural beings has both Buddhist and Hindu features. The Buddha and his monks, who are held in high esteem, are seen to help man's prospects in the next existence or in eternity, whereas the Hindu-influenced pantheon of supernatural beings is seen to hold sway over the present life and worldly prospects of men. Within this general framework, however, the supernatural beings who deal with this

world are divided into gods and goddesses who are thought to ensure long life, well-being, and fertility, on the one hand, and demons and demonesses who are thought to wreak havoc and to bring infertility, suffering, and death, on the other. Oversimplifying, their relations can be seen as the forces of light and darkness, or those of good and evil.

The place of magic in this picture becomes clear when we observe the elaborate precautions which are taken on the threshing floors at harvest time. The threshing floor is treated as the temple-residence of the gods and goddesses who try to increase the yield. The small circle becomes the battleground for the gods and demons over the fertility of the lands and the yield of the harvest. The demons and demonesses are feared to be hovering outside its borders, aiming to attack the grain on the threshing floor and to steal it. Special magical precautions are taken to please the gods and repulse the demons. Indeed, until recently Sinhalese peasants in the interior spoke a special language, which the demons could not comprehend, when they entered the sacred precincts of their threshing floors.

It is in this context that the role of sorcery is also seen most clearly. Just as there are elaborately developed techniques of communicating with the supernatural in the threshing floor to appease the gods and hold the demons at bay, there are also techniques, said to be very dangerous, to achieve the opposite. Logically, if the achievement of the good is within the bounds of human influence, so is the working of evil. Hence, Sinhalese villagers fully believe that some people can activate the demons against them by special offerings and incantations. Thus, sorcery is part of the very foundations of the total belief system of the villagers. And further, if there is sorcery, and if there are demons who are active, then men must seek magical protection. Indeed, the great theatrical art of ritual healing—directed specifically against sorcery—is one of the most noteworthy and developed aspects of folk culture among the Sinhalese (Wirz 1954; Yalman 1964).

Such precise linking of supernatural cause and effect, white magic and sorcery, sorcery and ritual healing is not always clearly visible in the detailed description of supernatural designs, but it appears likely that further analysis will reveal similar logical interlinkages in most primitive religions. As Evans-Pritchard observes for the Azande, "witchcraft, oracles and magic are like three sides of a triangle" (1937, p. 387).

The attempt to understand fully the inner workings of the mind of even the most primitive peoples is an obvious prerequisite to the analysis of their

supernatural beliefs, behavior, and rituals. Without such penetration into what appear to be irrational and alien mentalities, all observations are bound to be superficial, rash, or wrong. The process of understanding the minds of others is partly a matter of insight and freedom from prejudice, and although the discipline of anthropology has gone far in this direction, there is much room for improvement. In any case, the objective and respectful attempt to understand the inner logic in what superficially appears meaningless or illogical cannot be taken for granted. But the further question must also be raised of whether the linked and orderly system of ideas presented to us is really that of the native, or whether the order is artificially imposed on the phenomena by the mind of the anthropological observer. This issue is a difficult one, resting near the precipice of metaphysics, but its difficulty does not prevent the observation that the heuristic assumption of "system" in primitive ideologies has proved to be very fruitful. The claim regarding the systematic nature of primitive ideas is always open to further verification, but as yet no anthropologist has been able to sustain an argument based on the senselessness or illogicality of primitive beliefs.

In the meantime, further developments toward the understanding of belief systems have derived from structural linguistics. These are based on the desire not only to understand belief systems in a general way but also to go beyond the generalities and analyze the detailed features of belief systems on the model of communication systems (Lévi-Strauss 1964). Proponents of this approach maintain that belief and ritual systems have elements of order and internal structure because they form the framework for human communication. Lévi-Strauss (1955) has recommended examining the most minute details of primitive myths, as if they were literary texts. Other anthropologists have suggested that the sequences of ritual may be susceptible to the type of analysis that is applied to sequences of sounds in modern linguistics (Yalman 1964). These developments in the fields of mythology and ritual have an important bearing on magic, witchcraft, and sorcery; but as yet they remain promising methods rather than well-rounded and well-supported theoretical and analytic positions (Leach 1964). Their aim is the clarification of the structure of the language of mythology and ritual. Thus, they are formal analyses divorced both from Marxist opinions regarding the primacy of the social structure over systems of ideas and from the Freudian assumptions concerning the effects of the unconscious. Whether this line of inquiry will

prove effective remains to be seen (Lévi-Strauss 1963).

Structural aspects. We turn now to the effect of the beliefs in sorcery and witchcraft on social relations. The direct or veiled accusation of a person or a group is a critical element in the sorcery and witchcraft complex. Wherever these beliefs occur, we may expect a great elaboration of supernatural weapons of offense and defense against sorcerers and witches and these accusations.

There have been attempts to relate overt accusations of witchcraft and sorcery to the morphology of kinship or social groups. It is suggested that such accusation of evil intent of one person by another must run along the lines of stress in the structure of social groups. There is undoubtedly much truth in this statement, and it is confirmed by the widespread feeling among people of many cultures that institutions such as the evil eye, witches, and sorcery spring directly from one of the most powerful human sentiments, jealousy. This is merely a different way of expressing the strained social relations between the accuser and the accused. This is why jealousy and envy are so often given as the reason for the supernatural attack (Wilson 1951a). Witchcraft accusations that reveal both secret and unconscious envy as well as overt suspicions may be regarded as particularly clear symptoms of strain in the social structure.

One of the most interesting studies of this problem is by Nadel (1952). For purposes of precise comparison he selects two pairs of societies: the Nupe and Gwari of Nigeria, and the Korongo and Mesakin of the Sudan. Each pair is similar in most cultural respects but differs in a few critical structural features. Thus, in the Nigerian pair Nupe women are often traders, and their economic interest and activities put a well-recognized strain on husband-wife relations. Among the Gwari, the economic problems do not exist, and the strains are absent. Accordingly, although both cultures firmly believe in witchcraft, among the Nupe witches are conceived of as women, and witch associations are said to resemble women's trade associations. The Gwari, on the other hand, conceive of their witches as being both male and female.

In the second pair there is greater contrast. According to Nadel, the Korongo have no witchcraft beliefs at all, whereas the Mesakin are said to be totally obsessed by witchcraft. In general structural form the two groups are similar, except for some critical features which are singled out by Nadel. Both groups are matrilineal. Among the Korongo the age-class system permits easy mobility through the numerous classes for young men, whereas

among the Mesakin there are fewer grades and they remain closed and rigid. Among the latter, mobility is curtailed and is replaced by competition and hostility between the generations. The Korongo have no witch problems, whereas among the Mesakin most witchcraft accusations occur among maternal kin—more specifically, between mother's brother and sister's son, who are placed in positions of the most intense competition in the age-grade system.

In such theories the ideology and practice of witchcraft are related with some precision to areas of anxiety and stress in the social fabric. All these theories are based on the incidence of witchcraft accusations between individuals in certain specific social roles. But, for obvious reasons, statistical evidence of sufficient depth and range in connection with such highly charged issues is difficult to collect and evaluate.

Middleton and Winter (1963) have raised some important questions regarding both the coherence of dogma and the structural aspects of witchcraft and sorcery. Accepting the notion that witchcraft and sorcery have coherent doctrines which explain events in social life, they argue that sorcery and witchcraft beliefs are exhaustive systems of supernatural explanation. When found in the same society, moreover, they are opposed explanations. Theoretically, then, one set should be redundant; but in fact most African societies, they argue, have both systems of dogma. If so, they suggest, witchcraft and sorcery must fit in with different aspects of the social structure, and this hypothesis is related to the different natures of witchcraft and sorcery.

Since sorcery is a voluntary matter and merely a technique which can be learned, anybody may be in a position to use it for offense or defense. Moreover, depending upon the motives of the sorcerer, it is not innately evil. On the other hand, witchcraft is by definition an innate matter, usually evil, in which the alleged witch has no choice. For this reason Middleton and Winter suggest that witchcraft accusations are more characteristically made against persons who are in *ascribed* roles, such as involuntary membership in unilineal descent groups where the individual acquires his position by virtue of his birth, whereas sorcery accusations tend to be made against persons in *achieved* statuses and are more characteristic of the nonunilineal aspects of societies.

Thus, among Lugbara lineages, the women who come in as wives are incorporated into their husbands' patrilineages and become full members.

Even if they leave the husband, their future children legally continue to belong to his patrilineage. In this context the elaborate ideology of witchcraft is linked to women, and witches are always said to be females. Among the Nyoro, on the other hand, people live in mixed nonunilineal neighborhoods, the women are not incorporated into patrilineages, most social positions are voluntary, and there is a developed technology of sorcery rather than witchcraft.

Even though the specific application of these ideas is illuminating, it is difficult to generalize from them to witchcraft beliefs at large. For there is always an ascribed aspect to social status, and it appears difficult to evaluate the witchcraft of complex communities in early New England, medieval Europe, or present-day Indian communities of Middle America and South America in these terms.

Apart from the question of tension in social relations, the psychological aspects of witchcraft beliefs are another dimension of the facts. If witchcraft beliefs are regarded as unrealistic fantasies—a weak theoretical position from the point of view of anthropology—then some similarity and connection may be seen between witchcraft, sorcery, and infantile fantasies. But since these ideas, however unrealistic, are collective fantasies, their explanation can be related in any meaningful fashion only to collective infantile experiences. The question remains interesting but open.

The dogmas of witchcraft, sorcery, and magic are also relevant to the social control and inheritance systems of certain societies. Among the Trobriand Islanders the power of sorcery was an important weapon which buttressed the position of the chief. Although commoners had access to sorcerers, the chief could call upon the services of many in different districts and thereby extend his authority. Frazer has reported similar instances of the use of supernatural means to secure extensive reinforcement of traditional political organizations. The divine kingship of the Shilluk is one of the well-known instances (Evans-Pritchard 1948).

In some societies where witchcraft is regarded as an innate quality in certain individuals, there are theories of its inheritance. In some cases when the main line of descent, for purposes of family organization, is in the male line, witchcraft is thought to run in the female line.

Magic and social change

Ideas about magic and supernatural creatures play a vital explanatory role as organized and institutionalized systems of public belief in traditional

societies. They explain disease, injustice, misfortune, and death. Social reformers often feel that education may be used as the most potent weapon against such superstitions. It is true that modern education attacks these customary systems by providing alternative explanations for events and, probably more important, by undermining the authority of the spokesmen for the traditional system.

However, it is ironic that the fundamental changes in traditional society which permit the establishment of modern educational systems also bring about greater insecurity and increased tensions in social relations. Under such conditions, there is an even greater urge to turn to such supernatural weapons and beliefs as are available. It is notorious that modern governments in parts of Africa which have forbidden such practices as divination, the poison oracles, and similar traditional observances as being mere superstitions have naturally been seen as aligned with the forces of evil. For if the government prevents the use of appropriate traditional antiwitchcraft defensive weapons, they in effect frustrate the witch hunters and thereby materially contribute to the increase of witches. Hence, at least for parts of Africa, observers note that notwithstanding modernization, witches are felt to be more active and there is increased interest in modern movements of witch finders.

Magic, witchcraft, and sorcery are rooted in traditional customary ideas whereby cultures categorize and order the universe around them. As such, they not only are intertwined with every aspect of culture, thought, and language but also provide coherent and systematic means to influence the world in which man lives. For the anthropologist such belief systems provide essential material for the understanding of the metaphysics of non-Western cultures. They may also lead to a better understanding of the structured aspects of customary thought.

Ideas regarding witchcraft and sorcery appear strange in a rationalist period such as ours, but we should recall what immense sway such beliefs have held over very sophisticated and highly intelligent men. We must be guarded in our haste to dismiss these ideas of the supernatural. Rather, we must understand the very roots which provide the strength of conviction for such beliefs.

All knowledge rests on some degree of trust and respect. In modern societies the specialized task of developing knowledge and examining the basis of knowledge is given to thinkers and scientists in institutions of learning. Those not directly involved with a particular branch of investigation—if they

understand its language at all—take their conclusions on trust. The respect in which the institution is held is an important aspect of this trust. Similarly, the knowledge of supernatural powers, of gods and goddesses, of demons and demonesses, of sorcerers and witches in all primitive societies derives from respected traditions and institutions and from men who have proved themselves worthy of trust. Commonly shared beliefs are at the basis of communal sentiments, and hence beliefs which appear primitive and totally illogical to the Western observer not only rest on dogma but also take added strength from the fact that they are part of the moral foundations of the society in which they are found.

Alfred Thayer Mahan (1840-1914) was an American naval officer who wrote extensively on naval strategy and the history of sea power. From his studies of naval warfare he drew principles of strategy that greatly influenced the development and employment of naval forces during the first half of the twentieth century. As a historian he studied the relations of sea power and history, and he developed a philosophy of history in which the concept of force played a major role.

Mahan was born at West Point, New York, where his father was a professor of military engineering at the United States Military Academy. Mahan chose the navy for his profession and, graduating from the United States Naval Academy in 1859, saw active service in the American Civil War. At its conclusion, he continued his navy career and traveled widely. There was little indication during these years of the intellectual importance he was to attain.

Mahan was selected in 1885 to lecture on naval strategy, tactics, and history at the newly established Naval War College. He probably received the assignment because he wrote "The Gulf and Inland Waters," a competent volume appearing in 1883 as a part of a larger history of the American Civil War. His duties at the war college forced him to crystallize his thoughts on sea power and history. It was not his intention to do original research but rather to use the best historical works available to investigate his chosen field. From his lectures came the basis for his most important work, *The Influence of Sea Power Upon History: 1660-1783*, which appeared in 1890. There followed in 1892 *The Influence of Sea Power Upon the French Revolution and Empire: 1793-1812* and in 1905 *Sea Power in its Relations to the War of 1812*. He also wrote biographies and biographical sketches, as well as several interpretative articles upon events of his time.

A large number of his professional colleagues in the United States Navy did not recognize the importance of the task Mahan had set for himself. By his own choice, he retired from the navy in 1896 to pursue his literary career. He was a member of the naval war board that provided advice on strategy during the Spanish-American War. As a representative at the First International Conference at The Hague, he spoke against prohibiting poison gas, because he thought it inconsistent with permitting the use of the submarine torpedo. He was also instrumental in persuading American delegates not to sign the convention establishing

the Hague Permanent Court of Arbitration until a reservation was added safeguarding the traditional position of the United States against European involvement in the Americas and American involvement in Europe.

Concepts of naval strategy. Mahan defined sea power as the ability of a nation to control movement across the sea. He claimed that this control is the most potent factor in national prosperity and in the course of history. The components of a nation's sea power are geographical factors and national resources, the character of its people and its government, and its diplomatic and naval policies.

From his studies Mahan derived several strategic principles, having to do with the concentration of force, the choice of the correct objective, and the importance of lines of communications. Reduced to more concrete terms these principles mean that a nation should construct a battle fleet that has as its main objective the ability to destroy an enemy battle fleet. French naval history in the seventeenth and eighteenth centuries and the American experience during the War of 1812 led him to believe that cruiser warfare and raids against merchant shipping were of secondary importance. Until Mahan, however, such warfare had been the basic naval strategy of the United States.

Mahan's works appeared at a time when national rivalries were producing the international crises that culminated in World War I and when technological developments made possible the *Dreadnought*-type battleship which had only big guns. His works were avidly read by the British, the Japanese, and the Germans. In his own nation, he exerted influence in part by his writings and in part by his close friendship with such leaders as Theodore Roosevelt and Henry Cabot Lodge.

Mahan's theories of sea power remained cogent in naval strategy until the middle of the twentieth century. After World War II his concepts of sea power required modification. He had studied naval rivalries and fleet actions; consequently, his theories were applicable primarily when two or more powers were contesting the control of the sea. His principles did not easily fit the post-World War II situation in which the United States, controlling the sea, confronted the Soviet Union, controlling a large land mass. Nonetheless, his principles are still valuable in military analyses.

Military power and theory of history. It was perhaps inevitable that Mahan, with his background and professional concerns, should see military force as playing a dominant role in history. To him history was the revelation of the plan of

Providence. An integral part of this plan was the use of military force to preserve civilization and to right moral wrongs. It followed, therefore, that a nation could not blindly accept arbitration on all questions, for such arbitration might involve compromises on moral issues. Although Mahan saw history as a plan, he did not deny the individual a role: a military leader or a statesman can, by correct decision and action, shape events, but his power is limited by the materials with which he must work. Mahan, in his presidential address to the American Historical Association in 1902, issued a warning against too much research on detail, urging instead a careful grouping of facts and parts that would yield the truth of the whole.

Mahan was widely read in his own day. His emphasis on the role of the military and his call for expansion found resonance in the nationalism and imperialism of his time. While the basis of his philosophy was an orthodox, and even fundamentalist, Protestantism, the results of his thoughts were acceptable to the evolutionists of "the survival of the fittest" school. Historians feel that Mahan overstressed sea power and neglected the importance of other factors, but Mahan's contributions have not been erased. The strategic value of his principles has declined with the advent of the missile age and the nuclear weapon. Yet as both a historian and a strategist, Mahan influenced his own age and left a legacy of value to the future.

MAINE, HENRY SUMNER

Sir Henry Sumner Maine (1822-1888) was a lecturer on jurisprudence at Oxford and Cambridge, the founder of anthropological jurisprudence as an aspect of comparative law, a legal historian, and a colonial statesman. His enduring contribution to the social sciences is to be found in his formulation of the concept of ideal polar types and its uses in the comparative analysis of social phenomena.

Status and contract. In his works, especially in *Ancient Law* (1861), Maine contrasted early societies in which social relations are dominated by status with "progressive" (complex) societies in which social relations are predominantly determined by contract. By status Maine meant "a condition of society in which all the relations of Persons are summed up in the relations of Family" ([1861] 1960, p. 99). These relations are ascribed to the individual as a member of a kinship group. By contract Maine meant individual obligation arising "from the free agreement of individuals."

Although Maine explicitly declared that he could recognize no evidence that proved any society to be entirely destitute of the concept of contract, his major proposition was that in early societies the individual creates few or no rights for himself and few or no duties. Rather, he is subject to the traditional rules that govern his status and to new rules which are issued as commands by the head of his household.

Maine held that the primitive kinship group is patrilineal and autocratic. The commands of the household headman are the authoritative expression of the *patria potestas*. "In truth, in the primitive view, Relationship is exactly limited by Patria Potestas. Where the Potestas begins, Kinship begins; . . . here we have the reason why the descend-

ants of females are outside the limits of archaic kinship" (*ibid.*, p. 88).

The polar opposite to the patriarchally dominated, kinship-determined condition of status is the kind of social system exemplified by the complex Roman society during the time of Justinian. This kind of system is marked by contract-determined relations wherein the first person promises to perform acts or to observe certain forbearances and wherein a second person signifies his expectation that the first party will fulfill the proffered promise. The mental act of consensus is theoretically separated from the external formality of the ritual of the pact or convention (e.g., in transfers of possessions), and an obligation has been added which receives the full support of legal enforcement. This is true contract.

Maine wrote in the intellectual climate of eighteenth-century and nineteenth-century social evolutionism, and accordingly he set his model in an evolutionary mold. His polar types were designed not only to represent extremes in a range of variable social forms but also to describe development in the dimension of time. Hence the famous formula: ". . . we may say that the movement of the progressive societies has hitherto been a movement from *Status to Contract*" (*ibid.*, p. 100).

Because Maine worked exclusively with written historical records, his documentation of the evolutionary process was limited almost entirely to the Greco-Roman juridical experience. He judiciously defended this on the grounds that data on other ancient civilizations were scanty or altogether missing and that in any event Roman notions have so permeated most later systems as to preclude comparative study of crucial variations. Maine anticipated the concept of multilinear evolution when he expressed his belief that there can be no theory that accounts universally for the evolution of all social phenomena. Nonetheless, Maine concluded that "it may be reasonably believed that the history of ancient Roman Contracts is, up to a certain point, typical of the history of this class of legal conceptions in other ancient societies" (*ibid.*, p. 199).

In accordance with the concept of multilinear evolution, Maine proceeded to describe the steps by which the transformation from status to contract occurred. The life of ancient man in its earliest phases knew no custom, Maine believed, but was controlled by a regimen of caprice—the commanding judgments of the patriarchal family head or the king. These took the form of themistes—judgments on the individual case under the di-

rective of divine inspiration. ". . . It must be distinctly understood," Maine held, "that they are not laws, but judgments . . . they cannot be supposed to be connected by any thread of principle; they are separate, isolated judgments" (*ibid.*, p. 3).

Subsequently, in the process of social evolution the heroic king lost his sacred power and was politically displaced by a class of aristocrats who were not themselves royalty. In Maine's account, the early councils of aristocrats, although they abjured the claim to divine inspiration (except in Asia), nonetheless established the claim that they alone knew the body of principles in accordance with which quarrels were to be settled. In short, they became the repositories and administrators of law. Theirs was the "epoch of customary law."

The next phase, called by Maine the "Era of Codes," followed the invention of writing. The reduction of law to the written word ended the "spontaneous" growth of law, and all subsequent legal development was the product of deliberate effort to close the gap between changing society and frozen codes.

Maine was not content to assert the idea of social evolution; he undertook to demonstrate evolutionary mechanisms. The instruments of legal change, which permitted the modification of the forms of archaic law and the growth of modern law, were examined by him in great detail, under the rubrics of fictions, equity, and legislation.

Particularly significant is Maine's treatment of legal fiction, defined as any assumption which conceals, or affects to conceal, the fact that a rule of law has undergone alteration, its letter remaining unchanged while its operation is modified. Fiction makes legal change possible at a time when it cannot be overtly admitted that change is possible. Maine considered fiction to be a more primitive device than equity, which followed. Equity is distinguished by the fact that there is recourse to a new body of principles which are believed to have universal validity (as in *jus gentium* and natural law). It exists alongside the pre-existing civil law but supersedes it. The last mechanism of change to be developed was legislation. It differs from all previous sources of law, in Maine's view, because its obligatory force is independent of its principles. Its authority derives from an external body, existing as fiat.

In early twentieth-century social science, particularly in anthropology, Maine's theory of comparative law fared rather badly. Although he enjoyed some first-hand knowledge of the village community in India, there are no references in his *Ancient Law*

to contemporary nonliterate tribal society. Maine was content to interpolate a hypothetical state of universal social organization from the materials of ancient Greece and Rome. He had nothing to say about customs and law in any known primitive society.

To the modern social scientist, Maine's customless society is not only empirically nonexistent but theoretically impossible. It has not been difficult for ethnographers to prove invalid Maine's assumption of the initial universality of patrilineal, patriarchal social organization, characterized by absolute submergence of the individual within the corporate whole. Of 564 nonliterate societies in G. P. Murdock's "World Ethnographic Sample" (1957), less than half (44 per cent) are patrilineal, one-third are bilateral, and one-sixth are matrilineal (Aberle 1961, p. 665). The very simplest of these primitive societies tend to be neither patrilineal nor matrilineal. Furthermore, detailed examination of actual primitive systems has demonstrated that the patriarchal authoritarianism of the *patria potestas*, as it was known in early Rome, is not a common characteristic of primitive patrilineality.

Recent empirical anthropology, following R. H. Lowie (1920), has demonstrated also the extent of nonkinship groupings (clubs, fraternities, voluntary associations) and relationships in primitive society. Anthropologists have thoroughly established that Maine was wrong in his dogmatic assumption that the kin bond was the sole initial basis of political union and that its later subversion by the establishment of local contiguity as the basis of common political action was an antipathetic revolution. Geography as well as kinship is now known to be a more or less important factor in all sociopolitical systems.

Tort and crime. A second major formulation of polar opposites advanced by Maine was the contrast between the law of tort and the law of crime. "If therefore," he wrote, "the criterion of a *delict*, *wrong*, or *tort* be that the person who suffers it, and not the State, is conceived to be wronged, it may be asserted that in the infancy of jurisprudence the citizen depends for protection against violence or fraud not on the Law of Crime but on the Law of Tort" ([1861] 1960, p. 218). The test is the law of responsibility for initiation and carrying through of legal action; it is a test of procedure. Although there is a good deal more of criminal law in the law of primitive societies than Maine imagined, Maine's contrast is essentially correct. The general trend of the law, from primitive to civilized, is toward an increasing shift of

procedural responsibility from the individual as a member of a kinship group to the public officer as representative of the society at large.

Maine's influence. In spite of the antievolutionary reaction that almost submerged Maine, along with Lewis Henry Morgan, Tylor, and other social evolutionists of the late nineteenth century, Maine's working tool of ideal polar types was never wholly lost. Morgan used it to formulate his contrast of *societas* and *civitas*. Émile Durkheim used it to contrast the hypothetical isolated society of absolute homogeneity, bound by "mechanical solidarity," with the interdependent community ("the social organ") bound by the "organic solidarity" of interrelated, differentiated units. Through Durkheim, and through Tönnies' contrast of *Gemeinschaft* and *Gesellschaft*, Maine's influence on current French, German, and American sociology is clear.

As anthropology extends its interests beyond the illiterate tribe to the peasant community in the setting of civilization, interest in Maine is being renewed. The folk-urban continuum of Redfield and his followers is Maine's model with a new content. The extensive study of village communities in India and elsewhere, which burgeoned in the years following World War II, has revived Maine's work of comparative contrast, *Village-communities in the East and West* (1871).

In like manner, the current revival of interest in social evolution among anthropologists, as expressed in the writings of V. Gordon Childe, Leslie White, Julian H. Steward, and Marshall Sahlins, lends new vitality to Maine's work.

Above all, the problem of the economic and social development of recently independent underdeveloped nations has forced Maine's basic ideas once more to the fore. Economists, anthropologists, and sociologists have written extensively and emphatically to impress administrators of economic-development programs that African and Asian economic systems function as by-products of noneconomic institutions.

The most vigorous response to Maine's thought, relating to mid-twentieth century interests, is found in the writings of F. S. C. Northrop and his associates. Northrop goes beyond Maine, to hold that the concept of contract is a unique Roman invention, the product of Stoic lawyers creating, in the tradition of Greek mathematics, an imageless, logical-realistic universal concept. He attributes to the concept of contract the same significance for Western politico-legal development that the imageless constructs of Western scientific thought have for technical advancement and considers modern-

ization possible only if status-type social systems are replaced with universal contract relations.

In contrast, such men as Roscoe Pound and Morris Cohen, in their work earlier in this century with reference to trends within Western society, stressed countercontract developments in social and labor legislation that limit individual freedom of contract. Examples are workmen's compensation and minimum wage acts. Similarly, the standardization of contract terms in landlord-tenant, mortgage, insurance and other contracts is seen by some writers as substituting a group status-determinant for self-determination. Thus, when applied empirically to modern society, Maine's model is no more adequate than it proved to be when applied to actual primitive societies. In other words, contemporary empiricists have demonstrated that Maine's concept taken as absolute historical dogma will not stand up in detail; however, this does not mean that it may not be highly useful as a model of ideal types.

MAITLAND, FREDERIC WILLIAM

Frederic William Maitland (1850-1906), English legal historian and jurist, was born in London and died at Las Palmas in the Canary Islands, where ill-health had compelled him to winter since 1898. He was born into a family of intellectual distinction: his father was successively a fellow of Trinity College, Cambridge, a barrister, and secretary to the civil service commissioners; his mother was a daughter of a physicist, J. F. Daniell, a fellow of the Royal Society; his paternal grandfather, Samuel Roffey Maitland, barrister, clergyman, and for a short time the Archbishop of Canterbury's librarian at Lambeth Palace, London, was the author of 37 works, among them a remarkable book on medieval heresies (1832) that, in its skeptical attitude to accepted beliefs and its insistence on documentary proof, curiously anticipates the salient characteristics of his grandson's approach to history. From this grandparent, Maitland inherited, at the age of 16, a small property at Brookthorpe in Gloucestershire, which made him financially independent. In 1886 he married a niece by marriage of Sir Leslie Stephen (whom he commemorated in *The Life and Letters of Leslie Stephen* 1906), who was also the sister of H. A. L. Fisher, the historian and politician.

Education and academic career. With an excellent grounding in German from his governesses that was to serve him well in later life, Maitland went to Eton College in 1863, where his school life

was unremarkable and unremarked, and then in 1869 to Trinity College, Cambridge. There he abandoned his first interest, mathematics, in favor of moral and mental sciences, in which he was bracketed first in the final examination in 1872. A long-distance runner for his university and a skilled oarsman for his college, he was also president of the Union Society and already noted for his fluent and witty speech. Called to the bar as a member of Lincoln's Inn in 1876, he was professionally engaged for eight years afterward in the work of conveyancing and equity; his first publication, in 1879, "The Law of Real Property" (see *Collected Papers*, vol. 1, pp. 162-201), entered a sardonic plea for the abolition of cumbrous procedures, however sacrosanct the passage of time had apparently made them. Not until 1926 was this reform belatedly accomplished.

Maitland was slow to find his true vocation and to realize that to him the history of the law was much more attractive than its practice. Nevertheless, his course was being set by three essays: "The Laws of Wales: The Kindred and the Blood Feud" in 1881, "The Criminal Liability of the Hundred" in 1882, and "The Early History of Malice Aforethought" in 1883 (*ibid.*, pp. 202-229, 230-246, 304-328). Furthermore, he had in these years taken the momentous step of reading legal records in the Latin shorthand of the original manuscripts at the Public Record Office in London and as a result edited his first book, *Pleas of the Crown for the County of Gloucester Before the Abbot of Reading . . . 1221* (1884). Seeking entrance to academic life, he was rejected by Oxford but accepted by Cambridge in 1884 as reader in English law. He produced a magnificent three-volume edition of *Bracton's Note Book* (1887), defraying the cost of publication himself. It contained a collection of some two thousand legal actions between 1217 and 1240 that had been made for the great thirteenth-century judge Henri de Bracton to use in writing his monumental treatise *De legibus et consuetudinibus Angliae* (1569). This scholarly achievement led to Maitland's appointment as Downing professor of the laws of England at Cambridge in 1888.

The legal historian. Before Maitland's time, the history of English law had suffered from three main defects: its expositors, among whom the most worthy was John Reeves (*History of the English Law* 1783-1829), were overwhelmed by the austere technicalities of the law as it existed in their day and in consequence produced quite unreadable factual surveys; they isolated the subject from all other departments of learning; and they saw no

need to place it against its European background. Maitland wrought the great metamorphosis. Although he mastered the facts with infinite patience and used them constantly to provide concrete illustrations for his generalizations, he was interested above all else in the pattern of legal thought, particularly as it revealed itself in the origin and development of legal institutions. He insisted that the study of law, far from being a narrow, specialized discipline, provides the indispensable means of understanding the political, constitutional, social, economic, and religious history of the English people; he emphasized the value of comparative law, whether Roman and Germanic, Norman and French, Welsh and Scandinavian, and he placed the law of England firmly in the mainstream of European jurisprudence. In sharp contrast to William Stubbs, Maitland possessed the rare quality of mind that could free itself from the fetters of traditional concepts, whether about church or state, and reveal the way people of past eras defined the truth, thus making "the thoughts of men of the past thinkable to us."

Common law. To advance the knowledge of the history of English law, in 1887 he helped to found the Selden Society in London, and he sustained the burden of editing its early volumes until it had firmly established itself. Thus, he edited volume 1 of *Select Pleas of the Crown* (1888), *Select Pleas in Manorial and Other Seigniorial Courts* (1889), and *The Court Baron* (1891a), and he provided the introduction to *The Mirror of Justices* (1895). These volumes helped to prepare the way for the incomparable *History of English Law Before the Time of Edward I* (1895). Though ostensibly a joint work with Sir Frederick Pollock, this work was written entirely by Maitland except for a section on Anglo-Saxon law. Soon after, Maitland made his own investigations into the dark terrain of pre-Conquest England in his *Domesday Book and Beyond* (1897). In 1903 he committed the Selden Society to the formidable task of printing the Year Books, which recounted the arguments of counsel in the king's courts from the first years of Edward I's reign until the time of the early Tudors, and he himself edited three of them and coedited three (1903-1951). To assist the reader, Maitland made an elaborate study of the complicated accidence of law French and this has ever since elicited the praise of grammarians. Whether discussing the knotty problem of law enforcement (1885) or the obdurate persistence of custom (1898a) or compiling the charters of the borough of Cambridge (1901a), he never failed to focus a new and brilliant light upon

the many facets of English society in the Middle Ages. [See **LEGAL SYSTEMS**, article on **COMMON LAW SYSTEMS**.]

Canon law. Although not anticlerical, Maitland was, in his own words, "a dissenter from all churches" and remarkably free from ecclesiastical presuppositions. His *Roman Canon Law in the Church of England* (1898b) revealed a whole library of theological books as invalid; it controverted the Anglican legend of the Reformation, which had been espoused by Stubbs, by showing that English ecclesiastical courts had regarded papal law as authoritative and had failed to observe it in practice only because of state intervention. [See **CANON LAW**.]

Comparative law. To discover the interplay between English common law and Roman law before the fourteenth century, Maitland examined in minute detail, in *Select Passages From the Works of Bracton and Azo* (1895), how much the English judge was indebted to the jurist of Bologna. At Cambridge in his Rede lecture, *English Law and the Renaissance* (1901), he looked again at the influence of Roman law, this time in Tudor England. To support his distinction between the concept of the trust and what was known abroad as the legal corporation, he translated part of the third volume of Otto Friedrich von Gierke's *Das deutsche Genossenschaftsrecht* under the title of *Political Theories of the Middle Age* (1900) [see **GIERKE**].

The history of Parliament. Although unappreciated at the time, it is now beyond question that Maitland's introduction to the parliament rolls of 1305, printed as *Records of the Parliament Holden at Westminster* (1893), abandoned the long-hallowed belief that the early parliament was a "national assembly of estates" and introduced the modern conception that it was essentially "the king's council" in one of its many forms. Maitland here achieved another breakthrough, another destruction of old habits of thought, and his brilliant essay has formed the starting point of a whole series of parliamentary studies, still vigorously pursued.

Literary style. As an artist in words, Maitland followed no conventions and is himself inimitable. The severity of the subject matter and the vast erudition needed to cope with it did not prevent him from attaining a beautiful clarity in exposition. He seems to take the reader into his confidence and to converse with him, charming him with his exquisite sense of the perfect word and phrase, his happy epigrams, his gay humor. Yet he has been termed the "historian's historian." and it is true that

it was not simply literary merit that made him known to a wide circle: he probed deep below the surface in his preoccupation with analysis and rarely committed himself to writing narrative, although he did this with felicity in his chapter, "The Anglican Settlement and the Scottish Reformation" (1903).

Recognition. In the range of his interests, the fineness of his intellect, and the considerable bulk of what he wrote in barely twenty-five years, Maitland has no match among English historians. He was honored in his lifetime with doctorates from Cambridge (at the age of 41, while still serving that university), Oxford, Glasgow, Moscow, and Cracow; he was one of the first fellows of the British Academy; he was elected an honorary fellow of Trinity College, Cambridge, and a bencher of Lincoln's Inn; he was awarded the James Barr Ames medal by the Harvard law faculty. So highly was he revered that after his death, notes of his lectures were reassembled and published as *The Constitutional History of England* (1908), *Equity* (1909a), and *The Forms of Action at Common Law* (1909b).

Not all his views have been beyond dispute—for example, those on the garrison theory of borough origins, the superficiality of Bracton's knowledge of Roman law, the nature of corporations, the stability of the common law at the time of the Renaissance, and the Elizabethan religious settlement. Nevertheless, his reputation has increased, not dwindled, during the last sixty years: a historian can be paid no higher compliment.

MAJORITY RULE

The term "majority rule" stands for a rule of decision making within a specified group. At its simplest, the rule requires that the vote of each member shall be counted as equal to that of every other and that no vote or decision by a minority may override that of a majority. By extension, majority rule is sometimes contrasted with any rule requiring that decisions be unanimous or by any number larger than a simple majority. According to this extended version, then, not only may a minority never override a majority but also it can never *check* a majority: a majority vote is conclusive for the whole group. It is common to distinguish this usage by referring to it as "bare majority" rule, rule by "simple majority," or "strict majoritarianism." Within democratic regimes most of the controversies about majority rule relate to whether it is desirable to apply the "bare majority" rule at some particular stage of the political process, or even whether the ethical premises of democracy demand its application. For electoral purposes it is common, especially where a two-party system prevails, to permit choice (election) by a plurality that is less than a majority. Strictly speaking, this procedure violates the majority prin-

ciple, and such devices as run-off elections are often used to increase the probability that the elected candidate will have majority support.

History of theory and practice

Among the ancient Greeks, democracy entailed rule by majority vote of a popular assembly, of which all adult male citizens were members. Even in democratic Athens, however, there were institutional as well as practical limits on the power of majorities. A select group determined the agenda of the assembly, thus playing a significant role in framing the issues. Moreover, many important officials were selected by lot rather than by vote. This practice tended to limit the power of an organized majority or of a class or interest that comprised a majority, because in accordance with the laws of chance it gave proportionate representation to minority groups, as simple majority rule fails to do.

During the medieval period, whether in the great council of the church, in abbey chapter, or in secular parliament, decision by a bare or simple majority was slow to gain acceptance in practice and even slower to be vindicated in principle. The concurrence of all, the unanimity principle, seems universally to have been considered the ideal for positive action. It was common, however, to recognize that action could not be taken *against* the expressed wishes of a majority. (In this basic sense, majority rule prevailed.) The result was a kind of rule by "concurrent majorities" (Calhoun [1851] 1953, pp. 16-31). Typically, there was no fixed, mechanical formula for determining when a decision could be made, but unanimity was sought even if it could be obtained only by the process of wearing down and shouting down the dissenters—or by resort to threats or physical force. It was not until the sixteenth century that the ideal of unanimity and the practice of "veto groups" (the requirement of concurrence of the representatives of each town, county, etc.) gave way to the rule that the vote of a majority of individual representatives should prevail for positive as well as for negative action. Doubtless the rising individualism of this period, reinforced by the practical necessities of a state in which legislation was playing a far more important role than it had in the medieval period, led to this development.

The doctrine that the state should be based upon the consent of the majority of the people and that the specific acts of government should express the will of the majority (of adult males) was most systematically expounded and justified in the writings of John Locke (1690). Locke's fundamental

position was founded upon the equality principle, which he assumed to be self-evident and which seemed to him to dictate the majority principle as opposed to any form of minority rule. Popular acceptance of this decision-making rule, he felt, was based upon both convenience and the superior strength of a majority.

This theory spread rapidly and became the foundation of political liberalism. Rousseau adopted it, with the important refinement that he specifically indicated that the support of more than a bare majority for all important political decisions should be insisted upon, unless the urgency of reaching a decision dictated otherwise [see ROUSSEAU]. In England, Jeremy Bentham and the Utilitarian school accepted the equalitarian principle unquestioningly and, as a corollary, accepted also the rule that for all political decisions the concurrence of a majority should be a sufficient as well as a necessary condition [see BENTHAM]. The theory and practice of constitutional democracy, however, as it spread throughout most of the Western world in the nineteenth and twentieth centuries, generally recognized certain individual and minority rights and gave them some form of constitutional protection, thus placing limitations on bare majorities. [See CONSTITUTIONS AND CONSTITUTIONALISM.]

Contemporary issues

Today, within the context of democratic principles, majority rule as the rule for decision making is the subject of continuing analysis and discussion from two points of view. One debate relates to whether it is legitimate, from the point of view of the democratic ethic, to require more than a bare majority for certain decisions. The other area of discussion deals with the question of whether majority rule is, in any sense of that difficult word, the best, most "rational" technique for expressing the equality principle, maximizing satisfaction, or attaining any other posited objective of democratic government.

Merits of majoritarianism. Various writers have argued that the essence of the democratic ethic requires that the will (vote) of a simple majority should always prevail over the opposition. Any other rule, they urge, places a minority in a position to frustrate a majority and thus, in a sense, to rule. Accordingly, the logical and only legitimate derivative of the equalitarian, democratic assumption is held to entail bare majority rule.

Others defend the same decision-making rule on more pragmatic grounds. They maintain that a requirement, for any purpose, of more than a simple majority places undesirable obstacles in the way

of government. The dice are sufficiently loaded against progressive change without placing in the hands of self-interested or traditionally oriented minorities a powerful instrument of obstructionism. As long as opportunity for free association, discussion, and deliberation prevails, they argue, the rights of minorities will not be trampled upon. In a fluid and pluralistic society, a majority will not consist of a solid, fixed interest but will be made up of shifting coalitions of groups well aware of the fact that tomorrow they may be part of a minority and, therefore, sensitive to the interests and rights of minorities.

Opponents of strict majoritarianism advance numerous arguments. First, they point out that the majoritarian principle might be used to destroy the conditions of its own existence, such as freedom of association and expression. Moreover, other individual rights widely accepted as fundamental, such as the right to freedom of religion, the protection of fair procedure ("due process"), or property rights, might not always be respected by the majority. They also contend that bare majority rule is potentially unfair: it does not really institutionalize the equality principle, for instead of giving to the minority its rightful proportionate weight, it gives it none at all. The strict majoritarian position is questioned on still another ground: not only does it fail to give weight to minorities; it also takes no account of the intensity of interest or demand. Finally, quite apart from the equality principle, the desirability of rule by a bare majority may be challenged on purely pragmatic grounds. Where feelings are intense, a decision to override a large minority poses a serious threat to basic consensus. On the question of racial segregation in United States public schools, for instance, the minority feels so intensely that the basis for law and order itself is threatened when the attempt is made to compel complete integration.

Majoritarians have frequently argued in an abstract manner that renders at least part of their position so unrealistic as to be inapplicable in real life. If it is the majority that should in all situations and at every turn rule, because of the principle of political equality, presumably it is the majority of the electorate who should rule. In other words, nothing short of direct democracy could satisfy this condition, for representatives do not always express the will of the majority of their constituents. Even if each representative did always vote the wishes of a majority of his constituents and if all constituencies contained exactly the same number of voters, the majority might not rule because minorities might be unevenly dis-

MAJUMDAR, D. N.

D. N. Majumdar (1903–1960) was born of Bengali parents. He obtained a first-class master's degree in anthropology from the University of Calcutta in 1924. The training that he received there was in both cultural and physical anthropology, and to the end of his life he retained a broad interest in both the physical and the cultural aspects of the science of man. A large number of his papers and two of his books deal with anthropometric and serological studies among the tribes and castes of Uttar Pradesh, Gujarat, and Bengal.

"General anthropology" was not a mere slogan for Majumdar; it reflected his firm conviction that a unified science of man is not only desirable but also possible. Thus, in his analyses of social stratification in India, he emphasized the need to examine racial factors. Earlier H. H. Risley, in *The Tribes and Castes of Bengal* (1891a; 1891b) and *The People of India* (1908), had asserted a relationship between race and social groups in India; Majumdar gave further support to this view by his own extensive investigations. He showed that in Uttar Pradesh those castes which constitute "clusters," being close to each other in the hierarchy of castes, also fall within a narrow range of biometric variation (1949). Similarly, in his unpublished studies of growth among the school-children of Uttar Pradesh, he included a sociocultural factor as a significant variable.

The greater part of Majumdar's published work is ethnographic in nature and consists of accounts of the Ho (Bihar), the Khasa, the Korwa, the Tharu, and the so-called criminal tribes (all of Uttar Pradesh), the Gond (Madhya Pradesh), and the Bhil (Gujarat). He published monographic studies of both the Ho (1937) and the Khasa (1962). He knew the Khasa best and spent 22 summers doing field work among them.

Majumdar considered these studies to be contributions to cultural anthropology; he regarded social anthropology as a subdiscipline within cultural anthropology and not as an alternative frame of reference for the study of human social behavior. His approach to the study of culture was that of a functionalist. He went to England in 1933 to work for his doctorate at Cambridge, and he was awarded his degree in 1935. While in England he attended Malinowski's seminar at the London School of Economics and came under his abiding influence. Majumdar was also much influenced by the writings of Ruth Benedict (e.g., Majumdar 1944a). He stressed the integrated character of culture and maintained that cultural

stresses and strains are the outcome of a disturbance in a culture's "base." The "base" of a culture, he wrote (1937), is a function of four variables, namely, man, area, resources, and cooperation. If the disturbance is not of too fundamental a nature, a culture has a tendency to absorb the shock and revert to its original character; if otherwise, it changes to attain a new equilibrium (1958). His view of culture was thus essentially "integrationist," though not static.

Majumdar was the first formally trained Indian anthropologist to study the impact of nontribal cultures upon the ways of life of Indian tribes. This early interest in cultural change led him, in the 1950s, to welcome the emergence in India of rural anthropology. He played a notable part in this new field of research and produced one of the first book-length village studies in India (1958).

He also pleaded for the application of the findings of social science to the task of national reconstruction. As a member of the Research Programmes Committee of the National Planning Commission, he emphasized the help which anthropologists and sociologists could give to the administration by studying the problems of backward communities and by assessing the impact of government-sponsored projects of community development. His posthumous book on the Khasa (1962) contains a detailed discussion of the community development program in Jaunsar-Bawar (Uttar Pradesh).

It was Majumdar's deep belief in the utility of applied sociological research which made him undertake, in 1954, a survey of the industrial city of Kanpur in Uttar Pradesh (1960a). In this, as in many other personal and academic attitudes, he reflected the strong influence of Western social science. Although he did not visit the United States until 1952–1953, when he attended a Wenner-Gren Foundation symposium on anthropology and lectured at Cornell University, from quite early in his life he was receptive to ideas emanating from American universities. Thus, in his very first book (1937) he underscored the importance of studying the psychological dimension of human behavior, particularly in the acceptance and rejection of innovations.

Majumdar's ethnographic works are characterized by a richness and precision of detail, but they lack theoretical sophistication. This is probably due to the fact that almost the whole of his work in physical as well as in cultural anthropology was of a pioneering nature. More than any other individual of his generation, he endeavored to place anthropological studies in India on a scientific foot-

MALINOWSKI, BRONISLAW

ing. The success he achieved, considering the circumstances, was considerable.

At the time of his death, Majumdar was professor of anthropology and dean of the faculty of arts at the University of Lucknow. When he died, a book on polyandry among the Khasa was about to be published; at least one more (a village study) was ready for the publisher; and a research project on growth among schoolchildren in Uttar Pradesh was in progress. He was editor of the *Eastern Anthropologist*, a journal he founded in 1947. All these activities bear testimony to the breadth of his academic interests.

Bronislaw Kaspar Malinowski (1884-1942) was a Polish-born social anthropologist whose professional training and career, beginning in 1910, were based in England. Through his scientific activities, especially his methodological innovations, he was a major contributor to the transformation of nineteenth-century speculative anthropology into a modern science of man. As a fieldworker, a scholar, a theorist, and above all, a brilliant and controversial teacher and lecturer, he played a decisive part in the formation of the contemporary British school of social anthropology. An accomplished polemicist, he also attracted a wide audience to anthropology as a field of knowledge. Early in his own development he came to view anthropology as a field-oriented science, in which theory and the search for general laws must be based on intensive empirical research involving systematic observation and detailed analyses of actual behavior in living, ongoing societies. His principal field work was carried out among the Papuo-Melanesian people of the Trobriand Islands, located off the coast of New Guinea.

Malinowski's primary scientific interest was in the study of culture as a universal phenomenon and in the development of a methodological framework that would permit the systematic study of specific cultures in all their particularities and open the way to systematic cross-cultural comparison. He reacted strongly against the speculative reconstructions of both evolutionists and diffusionists and against the atomistic treatment of traits and trait complexes torn from their cultural contexts (1926a; 1929a; 1931a). In *The Dynamics of Culture Change* (1945) he insisted that culture change must be subjected to observation and analysis of the total interactive situation. [See CULTURE, article on CULTURE CHANGE.]

Malinowski was the originator of a functionalist approach to the study of culture. Although the idea of "function" is a key concept throughout his work—from his early scholarly research on the Australian aboriginal family (1913) to his final theoretical statement in *A Scientific Theory of Culture* (1944a)—his use of the term was open-ended, exploratory, and subject to continual modification. He treated culture as the assemblage of artifacts and organized traditions through which the individual is molded and the organized social group maintains its integration and achieves continuity. But he also treated culture as an instrumental reality and emphasized its derivation from human needs, from the basic universal needs of

the individual organism to the highly elaborated and often specialized needs of a complex society. In his view functionalism was a research tool, "the prerequisite for field-work and for the comparative analysis of phenomena in various cultures" (1944a, p. 175), that permitted the study of aspects of culture and the analysis of culture in depth. Through the intermediate analysis of institutions, a functionalist approach revealed the multilevel relationships between man as a psychobiological organism and man's creation, culture. [See FUNCTIONAL ANALYSIS.]

For purposes of research and exposition, Malinowski treated each culture as a closed system and all cultures as essentially comparable. However, he made little use of the comparative method, except illustratively. Rather, he treated the empirical study of a specific culture as a contribution to the understanding of the universal phenomenon of culture. In *Argonauts of the Western Pacific* he stated that the ethnographer's final goal must be

to grasp the native's point of view, his relation to life, to realize his vision of his world. We have to study man, and we must study what concerns him most intimately, that is, the hold which life has on him. . . . In each culture we find different institutions. . . . To study the institutions, customs, and codes or to study the behaviour and mentality without the subjective desire of feeling by what these people live, of realising the substance of their happiness—is, in my opinion, to miss the greatest reward which we can hope to obtain from the study of man. . . . Perhaps as we read the account of these remote customs there may emerge a feeling of solidarity with the endeavours and ambitions of these natives. Perhaps man's mentality will be revealed to us, and brought near, along some lines which we never have followed before. Perhaps through realising human nature in a shape very distant and foreign to us, we shall have some light shed on our own. (1922a, p. 25 in the 1961 edition)

Malinowski regarded residence among the people under study, competent use of the native language, observation of the small events of daily life as well as the large events affecting the community, sensitivity to conflict and shades of opinion, and a consideration of each aspect within the context of the whole culture as indispensable conditions to ethnographic work and, indirectly, to the sound development of theory. His demands on the fieldworker are very high; what is continually captivating is his expectation of the ethnographer's involvement simultaneously with "these natives" and with "man." [See ETHNOGRAPHY.]

Intellectual background. Malinowski was born in Cracow in the region of Poland that was then politically part of the Austro-Hungarian empire. His father, Lucyan Malinowski, 1839-1898, an emi-

nent Slavic philologist, was instrumental in bringing modern linguistic studies to Poland and also did work in ethnography and folklore (Symmons-Symonolewicz 1959). Bronislaw Malinowski grew up at a time and in a setting in which central European intellectuals were deeply aware not only of their special cultural heritage (which led many to an intense political nationalism) but also of the multilingual, multicultural milieu in which they moved. Malinowski had a gift for language, and like many intellectuals of his background, he had a wide command of modern languages, including Polish, Russian, German, French, English, Italian, and Spanish. In terms of his background, it is illuminating that his scientific interest in language centered on language as a mode of behavior and on problems of culturally determined meaning. In the same period that Franz Boas returned to the field to study types of speech, using new recording devices, Malinowski predicted the use of sound film for the study of "fully contextualized utterances" (1935a, vol. 1, p. 26).

His early experience certainly contributed to his assumptions about cultural uniqueness and the comparability of all cultures, assumptions that are not fully spelled out or tested in his work. They are, of course, crucial to his use of a single primitive culture, that of the Trobriands, as his vehicle of methodological exploration and analysis. However, in seminar discussions he drew—and encouraged his students to draw—on a wide range of complex cultures for contrast and comparison. Both forms of exposition delighted him.

Malinowski's initial training was in physics and mathematics, in which he took his Ph.D. in 1908 at the Jagellonian University in Cracow. Ill health, which pursued him all his life, forced him to terminate work in these fields. Then, "as the only solace to his troubles," he began to read, in English, the three-volume edition of Frazer's *The Golden Bough* and discovered that "anthropology . . . is a great science, worthy of as much devotion as any of her elder and more exact sister studies" (1925a, pp. 93-94 in the 1954 edition).

For a brief period he studied at the University of Leipzig (where his father had earlier received his doctorate) and, working under Wilhelm Wundt and Karl Bücher, came in contact with current ideas of experimental psychology and historical economics. But in 1910, when he went to England as a postgraduate student at the London School of Economics, he already had his research on Australian aboriginal culture under way (Barnes 1963, p. xii) and probably his book on primitive religion and forms of social structure, later published in Poland (1915a).

Work on kinship. British anthropology was lively and contentious then, and Malinowski's work was responsive to the crosscurrents of thought. *The Family Among the Australian Aborigines* (1913) is a magnificent tour de force in its use of a vast patchwork of source materials to make the point (doubtful to those who looked upon the peoples of Australia as the living exemplars of an earlier stage of man) that these peoples had "individual marriage." Characteristically, Malinowski had another aim: "It is not the actual relationship, or the individual family, or 'family in the European sense'. . . . It is the aboriginal Australian individual family, with all its peculiarities and characteristic features, which must be constructed from the evidence" ([1913] 1963, p. 8). Westermarck's influence on his thinking is clear [see the biography of WESTERMARCK]. But he also raised the question of how to "find in all this complexity the structural features, the really essential facts, the knowledge of which in any given society would enable us to give a scientifically valid description of kinship" (*ibid.*, p. 198). Family and kinship, the unique culture and the universally applicable method, these are constant themes in his work.

This study is chiefly valuable today as a period piece and as a source book on Malinowski's thinking at the outset of his career. However, his handling of the data and choice of subject matter are measures of his virtuosity and unerring ability to select as the carrier of his own ideas a problem attractive to fellow scientists and a wider audience as well. [See KINSHIP.]

Field research. His interest now shifted to field research in New Guinea, an area that was being opened up by A. C. Haddon, W. H. R. Rivers, C. G. Seligman, and others who influenced his thinking. His training in scientific method and the fine detail of his scholarly work peculiarly fitted him for a part in developing the new techniques of intensive field research. Mainly through Seligman's efforts, he obtained a Robert Mond Travelling Studentship (University of London) and a Constance Hutchinson Scholarship (London School of Economics). Thus equipped, he went out to New Guinea via Australia, where he attended a meeting of the British Association as a guest of the Commonwealth government (which later made him a supplementary grant). In view of the cost of modern field research, it is enlightening to realize that over the six-year period 1914–1920, he had available for field work, data collection, and writing "little more than £250 a year" (1922a, p. xix in the 1961 edition).

His first expedition, September 1914 to February 1915, was to the Mailu of Toulon Island. Already

familiar with the structure of Melanesian languages—in *Coral Gardens and Their Magic* (1935a, vol. 1, p. 453), Malinowski described his progress in learning these languages—he spent four weeks in Port Moresby working on pidgin English and Motu, the lingua franca used by the Mailu. His report on the Mailu (1915b), together with his Australian researches, earned him his D.Sc. in 1916. But in later years he discounted this first field work. He found the Mailu "coarse and dull" (1922a, p. 34 in the 1961 edition). What excited his interest were their accounts of the Massim, to the east, from whom came handsome objects, lively songs and dances, and fearful tales of sorcery and cannibalism. Yet his report on the Mailu is of interest, since it documents not only his use of a conventional framework but also his attempt to use new kinds of ethnographic subject matter (for example, his observations of daily life), his difficulties in coming to grips with the problems of working in an ongoing society, and his leap ahead in recognizing essential conditions for field work. The necessity of working through an interpreter and an intermediate language was a particular source of frustration.

Returning to Australia, he paused briefly on Woodlark Island, where he hoped to work later. Instead, his second expedition, from June 1915 to May 1916, took him to the Trobriand Islands. He set up his tent in Omarakana, the village in which he began his work. By September he had dispensed with an interpreter and was using Kiriwinian, the Trobriand language. But he could follow fast conversation and take notes in the language only on his second Trobriand field trip, from October 1917 to October 1918, after he had organized his first year's notes (1935a, vol. 1, p. 453).

Between field trips he wrote his first account of the culture, "Baloma: The Spirits of the Dead in the Trobriand Islands" (1916). In retrospect, it is clear that he had now found his subject, his style of work, and his characteristic mode of presentation. In this essay he described in vivid detail the afterlife of the spirits (*baloma*), their relations to the living, their return visits at feasts in their honor, and their reincarnation. In one digression he discussed magic spells, the use of ancestral names in magic, and the inheritance of magic in this matrilineal, patrilocal society. Another dealt with Trobriand ignorance of physiological paternity and his struggle in the field to clarify Trobriand belief. In the final section he discussed the fieldworker's problem of bringing order into the "chaos of facts"—here referring to the diversity of views, the different levels of knowledge, and the various types of emotional response among different indi-

viduals. Fresh from the field, he was convinced that "no 'natives' [in the plural] have ever any belief or any idea; each one has his own ideas and his own beliefs" (1925a, p. 240 in the 1954 edition). The ethnographer, studying the "social dimension" in all its complexity, must find ways of systematizing the diversity of formulations and of extricating ideas and beliefs from native behavior and the institutions in which they are embedded. He wrote that "field work consists only and exclusively in the interpretation of the chaotic social reality, in subordinating it to general rules" (*ibid.*, p. 238). [See FIELD WORK.] Finally, he defined the opposition between "individual ideas" and "the dogmas of native belief, or the social ideas of a community" that must be "treated as invariably fixed items" (*ibid.*, p. 244), and so he laid the groundwork for his later discussions of myth, magic, and religion. But even as he acknowledged his indebtedness to Durkheim and his school, he rejected the concept of "collective ideas" as incompatible with the reality of the "aggregate of individual souls" in a community (*ibid.*, pp. 273-274, n. 77). This highly selective way of handling the theories of his predecessors, in which he transformed what he accepted, was characteristic of Malinowski's approach, especially in his polemical writings.

This essay exhibits the mosaic quality that is typical of Malinowski's exposition. He stated a theme, he developed it in narrative form around an institution, a set of institutions, or the activities relevant to an aspect of the culture, and at different stages, he interpolated data on other aspects, other activities. Thus, step by step he progressed toward abstraction. On a larger scale the whole of the work on the Trobriands forms a very elaborate mosaic, no part of which stands wholly alone. The successive discussions are not serially linked; instead, his analysis grows by expansion and elaboration, over time, with the elaboration of his own thinking in the process of organizing the data. Yet each work, like this first long essay on the spirits of the dead, is characteristic of the whole.

A large part of Malinowski's work consists in the attempt to develop principles and create models for just this intermediate stage of interpretation, using Trobriand culture as his laboratory. One of the persistent criticisms of his work is that it is "overloaded with reality" (Gluckman 1947, p. 15). But it is with the ordering of this reality that he was concerned.

Career in London. In October 1918 Malinowski returned from the field to Australia. There he married Elsie Masson. He did not immediately go

back to London but for reasons of health spent a period on Tenerife in the Canary Islands, where he worked on *Argonauts of the Western Pacific*.

He had first begun to lecture at the London School of Economics in 1913; in the early 1920s he again began to give short courses. In 1924 he was appointed to a readership in anthropology and in 1927 to the first chair in anthropology at the University of London. With the publication of *Argonauts* (1922a) his position as a scientist was secure, and he began to acquire an international reputation. The next 15 years, 1923-1938, were his most productive ones as a writer and as a teacher who drew into his seminars an ever-increasing number of talented and mature students, research workers, and professionals from various fields.

Describing Malinowski's relations to his students, Audrey I. Richards wrote:

He tended to regard them rather as a team engaged on a joint battle than as a number of individuals with different interests and needs. They learnt a particular method of work and a particular theoretical interest, rather than a body of detailed facts. . . . It was in seminars that his teaching gifts were best displayed. These weekly discussions became famous, and attracted students of the most different types. Colonial officers on leave valued Malinowski's live approach. . . . Senior research students came from many parts of the world, and Malinowski would often flash retorts in four or five different languages. University lecturers sat side by side with the veriest amateurs. . . . There was a curious kindling touch in all he did, and a rare power of evoking ideas in others. (1943, p. 3)

Malinowski's teaching methods reflected his own quick responsiveness and his need for response in others. Intellectual pretense he treated with caustic contempt, but he had unexpected resources of patience and gentleness in his relations with able, still inexperienced and self-doubting students. As more mature students progressively measured themselves against his standards of intellectual complexity, skill, and originality, he could be in turn ruthlessly witty at their expense, provocative, and devastatingly critical of what he valued most in them, their capacity for independent judgment. His most able students in time responded with anger and self-assertion mixed with admiration and devotion, a complex of attitudes that is evident in their later, very careful assessments of his work (Firth 1957; Gluckman 1947).

Malinowski's publications in his London years fall into several groups which, while overlapping, indicate his varied interests.

First, there are his major works on the Trobriand Islanders. *Argonauts of the Western Pacific*

is an analysis of Trobriand economics through the study of overseas trading expeditions in the highly formalized *kula* ring, in which the circular exchange of "valuables" provided a setting for trade and communication [see ECONOMIC ANTHROPOLOGY]. *The Sexual Life of Savages in North-western Melanesia* (1929b) is an exposition of the individual's induction into the adult life of marriage and the family. Here Malinowski worked out in the field what he had glimpsed through his study of the Australian aboriginal family, and even today it is one of the most detailed and acute analyses of how, in one primitive society, cultural tradition molds individual behavior in the most highly emotionally charged aspect of personal life. *Coral Gardens* (1935a), Malinowski's most sophisticated and self-critical work, deals with the organization of Trobriand social life through activities related to horticulture, the place of magic in the belief system, and the integrative aspects of gardening. In this work Malinowski also presented the most sustained exposition of his linguistic approach through analyses of gardening spells.

In a second group of publications, including "Magic, Science and Religion" (1925a), *Crime and Custom in Savage Society* (1926b), *Myth in Primitive Psychology* (1926c), and *The Foundations of Faith and Morals* (1936a), he took up, and on several occasions returned to, topics that had long provided controversial issues. Each statement is, among other things, a demonstration of the transforming effect of detailed field work on the criteria of what is relevant to the delineation of a problem. Perhaps in no other context does Malinowski give such clear evidence of his position as a transition figure in social science. For in these essays he breaks new ground not in his choice of topic but in his dazzling use of field data. Yet, though he looks forward in this, he remains linked to the past in his use of very limited data to generalize about primitive culture and man.

Magic, science, and religion. In his handling of science, magic, and religion, Malinowski essentially accepted the traditional Western conception of a dual reality—the reality of the natural world, grounded in observation and rational procedures, that lead to mastery, and supernatural reality, grounded in emotional needs that give rise to faith. Unlike Frazer, for example, Malinowski derived science not from magic but from man's capacity to organize knowledge, as demonstrated by Trobriand technical skills in gardening, shipbuilding, etc. In contrast, he treated magic, which coexisted with these skills, as an organized response to a sense of limitation and impotence in the face of danger,

difficulty, and frustration. Again, he differentiated between magic and religion in defining magical systems as essentially pragmatic in their aims and religious systems as self-fulfilling rituals organized, for example, around life crises. Significantly, he differentiated between the individual character of religious experience and the social character of religious ritual. In his analysis he linked myth to magic and religion, not as an explanation but as evidence of the authenticity of the magical act and the religious dogma. Particularly illuminating is his discussion of the use of public magic in the Trobriands as an initiating act in the organization of stages of work. *The Foundations of Faith and Morals* represents an attempt to apply hypotheses based on primitive cultures to the problems of European societies [see MAGIC; see also Nadel 1957].

Anthropology and psychology. Throughout his career Malinowski sought for a systematic psychology on which he could draw in establishing a dynamic relationship between man and culture. In the 1920s Freudian theory had a profound, if somewhat diffuse, influence on his thinking. As Meyer Fortes has pointed out (Firth 1957, pp. 157–188 *passim*), Freud's hypothesis about the Oedipal situation provided Malinowski with a psychological framework for developing his own analysis of the relationship of father, son, and maternal uncle in Trobriand culture. Although he later turned against psychoanalysis, such publications as "The Psychology of Sex" (1923a), "Psycho-analysis and Anthropology" (1924), *The Father in Primitive Psychology* (1927a), and *The Sexual Life of Savages* (1929b), in which he incorporated much of the earlier material, indicate the creative use he made of psychoanalytic concepts and some of the difficulties he faced in trying to transform psychological into cultural process. Even though Malinowski derived culture ultimately from man's needs, he eventually gave precedence to cultural tradition as the primary influence in the molding of the individual. In his last years at Yale he was attracted by Hullian learning theory (1944a); in fact, however, it had little effect on the core of his thinking. [See CULTURE AND PERSONALITY.]

Culture change. In the late 1920s Malinowski began to turn his attention to problems of culture change and the development of a "practical anthropology" as a field tool. Although he himself was called on for expert advice and his students, working in Africa, were brought face to face with the difficulties of research in rapidly changing societies, his approach was essentially schematic and exploratory (1945). Aside from a four-month trip

in 1934 to visit his students' field sites in Africa, he lacked the crucial experience of relevant field work.

Career in the United States. In 1938 Malinowski came to the United States on sabbatical leave. The death of his wife in 1935 after a long illness had broken the thread of his personal life in London. This was not his first visit to America. In 1926 he spent some months there at the invitation of Lawrence K. Frank of the Laura Spelman Rockefeller Memorial. At that time he traveled, taught briefly at the University of California, and visited the Hopi Indians in the Southwest. In 1933 he delivered the Messenger lectures at Cornell University. In 1936 he came as a delegate of the University of London to the Harvard Tercentenary celebration, at which he delivered an address on culture as a determinant of behavior (1936*b*; 1937) and was awarded an honorary D.Sc.

After October 1939 he was at Yale University, first as visiting professor, from 1939 to 1940, and then as Bishop Museum visiting professor, from 1940 to 1942. His marriage to Valetta Swann, the painter, in 1940 opened the way to new companionship and happiness.

Nevertheless, the years at Yale were very difficult ones. In the United States he was a stranger, celebrated and sometimes lionized, but a man in exile. For the most part, his Yale students were far less mature than his students in London. They were unfamiliar with his work, and his European point of view seemed no less exotic to most of them than American manners seemed to him. The necessity of beginning his teaching from the beginning again did not stimulate him. The simplified form in which he presented his theoretical system in *A Scientific Theory of Culture* (1944*a*) reflects his detachment. His strictly theoretical presentations (1926*a*; 1929*a*; 1929*c*; 1929*d*; 1931*a*), though elegant, are somewhat bare in comparison with those in which he was arguing or working toward abstraction, but his last and most extended statement is also curiously tentative.

In the 1930s he had become progressively alarmed at the dangers presented by totalitarianism. Like many intellectuals, he worked unsparingly to alert people to the possibility of "a period of dark ages, indeed the darkest ages of human history" (1944*a*, p. 15). Advised not to return to wartime England, he worked passionately on behalf of the democratic cause and a postwar international world order.

In 1940, in spite of ill health, he began a new field project, a study of marketing among the Zapotec of Oaxaca. He planned a series of studies, each from a special stance, and made two field

trips in the summers of 1940 and 1941. In between, he worked closely with a young Mexican colleague, Julio de la Fuente, an experienced and accomplished fieldworker. The work promised methodological innovations. In 1942 he received a permanent appointment at Yale, effective in October. He died on May 16 of that year, in the midst of ongoing work.

Assessment. Malinowski's place in anthropology is as yet exceedingly difficult to assess. In the years since his death, much of his theoretical work has been bypassed. Certain of his ideas that made him a storm center in the 1920s have been so fully incorporated into anthropological thinking that his exposition now appears unnecessarily didactic. He was an innovator, but the very necessity of breaking through older conceptions kept his attention focused on issues and problems that were absorbed or transformed by the new methods of observation and analysis and the new theoretical formulations that developed out of his own work and that of his students. Nadel pointed out that "at some stage, someone must ask, and attempt to answer, those 'big' questions if empirical work is to proceed systematically and fruitfully" (1957, p. 190). The necessity of doing so in ways that were relevant to a field-oriented science kept Malinowski a generalist even as he trained his students to become specialists. Nadel spoke for others among Malinowski's students when he said, "Today, we have grown much more modest, but also more conscious of the need for precision and solid empirical evidence" (*ibid.*, p. 189). It was Malinowski's breadth of vision that made this advance possible.

The contribution which his students, even the most critical of them, value is his comprehension of the total field situation and his ability to communicate to others the complex interplay of problem and reality. The actual period of time Malinowski spent in the field was astonishingly brief—only two and one-half years in New Guinea. But in one sense his lifework was a continual renewal and re-creation of this experience.

His method of institutional analysis made it possible for him to express, through a model, certain core ideas of his theory: the integrity of each culture; the complex interrelationship of the society, the culture, and the individual; the grounding of culture in the human organism (in man's needs and capacities and in the individual as the carrier of culture); and the systematic nature of culture as a phenomenon. He treated the institution as the unit of analysis; whatever its difficulties in application, it indicates how complex any "unit" of analysis must be.

Malinowski's theoretical framework is a major contribution. However, no anthropologist today is prepared to make the dizzying leap from the particular to the universal that characterized his attempt to create an effective methodology. There are essential intermediate steps. These involve, for example, intensive studies of process within and across cultures and over time. We require also fine-grained systematic comparison of intensively studied cultures and cultural process. Today we are acquiring the tools (for example, the sound-film recording devices Malinowski himself foresaw as necessary in studies of communication) that are making more delicate and systematic research feasible. Malinowski's search for an adequate psychology was a step toward broadening the base of empirical research. But collaboration among all the relevant sciences will be necessary. The study of culture is crucial to, but not in itself sufficient for, the development of a science of man.

Malinowski's attempt to formulate theory on the basis of limited data places him in extreme contrast with his older contemporary Franz Boas, as does his almost exclusive preoccupation with a theory of culture. Boas had a very broad experience, beginning early in his career, in planning for and administering research, in much of which he was personally involved, in the whole field of anthropology. Necessarily, he worked within a comparative framework in space and time, and with full awareness of the importance of carefully recorded detail. Like Malinowski, he had the natural scientist's commitment to the formulation of general laws, but in his case, concern for long-term gains made him extremely dubious of the value of theoretical formulations based on partial evidence.

In the history of a science it is necessary to take into account the temperamental as well as the experiential differences among innovators. It is possible that the tensions necessary for the development of new thinking arise from just such differences. Malinowski's impact on a whole generation of anthropologists—like that of Boas—was a measure of his capacity as a thinker and a teacher to evoke in others a clear perception of the state of the science and confidence in the value of their own work. It remains to be seen whether their successors can resolve these tensions through research that will shape new aims.

MALNUTRITION

See FAMINE and FOOD.

MALTHUS, THOMAS ROBERT

Thomas Robert Malthus (1766-1834) was born ten years before the publication of Adam Smith's *Wealth of Nations*, and his work as an economist belongs to the broad tradition established by Smith's treatise. After being privately educated, Malthus entered Jesus College, Cambridge, where

he was elected to a fellowship at the age of 27. He took orders in 1797 and held a curacy for a short period. He married in 1805 and shortly thereafter was appointed professor of modern history and political economy at the East India Company's college at Haileybury, the first appointment of its kind in England. He died at Haileybury in 1834, the year that saw the passage of a new poor law inspired by his writings.

Malthus' father was a friend of Rousseau and shared the optimistic belief of Condorcet and William Godwin that nothing stood in the way of a regime of ideal equality but private ignorance and public inertia: propaganda and education were therefore the means for bringing about perfect happiness. The younger Malthus disagreed and argued that the effort to realize the perfect human society would always founder on the tendency of population to outrun the food supply. His father urged him to put his ideas on paper, and in 1798 Malthus published a long pamphlet entitled *An Essay on the Principle of Population, as It Affects the Future Improvement of Society; With Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers*. There was nothing original in Malthus' argument. It had all been said before, albeit with less force. Nevertheless, Malthus was attacking the dominant contemporary view, which saw underpopulation rather than overpopulation as a problem. When the first census, in 1801, produced evidence of a sharp rise in population growth in recent decades, Malthus decided to take advantage of the change in the climate of opinion by turning his pamphlet into a book (published in 1803) with a new subtitle that implied a change in emphasis: *A View of Its Past and Present Effects on Human Happiness With an Inquiry Into Our Prospects Respecting the Future Removal or Mitigation of the Evils Which It Occasions*. What had started out as an occasional tract against certain dangerous ideas held by some contemporary thinkers had become a full-scale treatise on the subject of demography. Further revised editions of the book were published at regular intervals during his lifetime, the sixth edition appearing in 1826.

Although Malthus' fame in the nineteenth century was based squarely on his theory of population, his modern reputation with economists rests rather on his prescient opposition to the Ricardian doctrine of the impossibility of "general gluts." As Keynes put it in *The General Theory*: "Ricardo conquered England as completely as the Holy Inquisition conquered Spain," in consequence of which, "The great puzzle of Effective Demand with which Malthus had wrestled vanished from eco-

conomic literature" (1936, p. 32). Malthus' ideas on gluts, or, as we would now say, business depressions, were embodied in his *Principles of Political Economy*, first published in 1820. Other minor but significant publications on strictly economic questions are *An Inquiry Into the Nature and Progress of Rent* (1815); *The Measure of Value Stated and Illustrated* (1823); and *Definitions in Political Economy* (1827).

Demographic ideas. Malthus' theory of population is baldly stated in the first two chapters of the *Essay*. These pages are brilliantly written in terse phrases and striking images, and they help us to understand why the book captured the imagination of its first readers, rousing a storm of controversy that never died down during Malthus' lifetime. The thesis itself is familiar enough, although all of its implications are not immediately evident: population, *when unchecked*, increases in a geometrical ratio, while the food supply at best increases in an arithmetical ratio; hence, population tends to increase up to the limits of "the means of subsistence." This is the principle of population that Malthus maintained against all his critics. He realized, of course, that in the real world there are checks that prevent population from increasing beyond the food supply. The checks are of two kinds: "positive" checks that show up in the death rate, such as war, famine, and pestilence; and "preventive checks" that show up in the birth rate, such as abortions, infanticide, and birth control. Both checks are the consequences of lack of food, which may, indeed, be regarded as the ultimate check on population growth that is always in operation.

Such was Malthus' argument in the first edition of the *Essay*. Its weakness was quickly discovered by Godwin, who pointed out that the working classes in the richer countries seemed to be maintaining themselves at a level considerably above the physical minimum of existence, without benefit of either the positive or the preventive checks. Malthus, realizing that he had trapped himself by denying the possibility of any rise in the standard of living, quietly gave way in the second edition of the *Essay* by recognizing the existence of a new preventive check, namely, "moral restraint." He defined "moral restraint" as postponement of the age of marriage accompanied by strict sexual continence before marriage, and, while the other checks were frequently described as "misery" or "vice," the new preventive check was allowed to stand alone without any pejorative tag attached to it. For the first time a hopeful note crept into the argument, although Malthus himself always remained pro-

foundly pessimistic about the capacity of mankind to regulate its numbers by the exercise of prudential restraint. Few readers realized that he had really abandoned his original thesis, and Malthus did nothing to help them appreciate the escape clause that had now been built into the doctrine.

Any critic who produced evidence of subsistence increasing faster than population without signs of "misery" or "vice" was silenced by the logical implication that the working class must be practicing "moral restraint," a phenomenon included in the theory. This left the critic with no reply other than to show that the average age of marriage had not increased or that the rate of illegitimate births had not fallen. Since contemporary population statistics were not adequate to verify such assertions, Malthus had furnished himself with an impregnable defense. There were a few critics who attacked the theory by questioning the notion that birth control constitutes "vice." Malthus' argument here was simply that birth control must be wrong, since man, being naturally indolent, could hardly be expected to work or save if it were made so easy for him to escape the consequences of his "natural passions." He was confident of the support of contemporary opinion in lightly dismissing what were later called neo-Malthusian checks, "both on account of their immorality and their tendency to remove a necessary stimulus to industry" ([1798] page 512 in 1878 edition).

Some hostile critics realized the futility of denying that unchecked populations tend to increase at a geometrical rate, inasmuch as no one had ever observed the growth of an unchecked population. Instead, they attacked the idea that the food supply could not possibly keep pace with the irrepressible tide of population. Here Malthus had recourse to the principle of diminishing returns in agriculture—in fact, he was one of the first to state this general principle in so many words. Since this principle soon became an integral part of orthodox political economy via Ricardo's theory of rent, it was difficult to criticize Malthus on this score [see RICARDO]. We realize now that Malthus was actually appealing not to the impeccable Ricardian law of diminishing returns to variable factor increments in a situation of given technical knowledge, but to a questionable historical law of diminishing returns from technical progress in agriculture. But the distinction between statics and dynamics was so little understood in those days—even Ricardo switched easily from static analysis to historical generalization, sometimes in the same sentence—that Malthus had no difficulty in meeting criticism along these lines.

The utter simplicity and familiarity of the ideas involved, calling neither for new concepts nor for new facts, was the essence of Malthus' popular appeal. All he seemed to be doing was to bring together a few familiar facts of life and to deduce the necessary consequences of these facts. Surely it was true that population nearly always multiplied up to the limits of the available food supply. And surely, where living standards had improved, the gain was necessarily precarious and always liable to disappear in a new spurt of population growth. Was it not self-evident that an unchecked multiplication of human beings must quickly lead to an impossible situation, whatever the plausible rate of increase of the means of subsistence? The contrast that Malthus drew between the two kinds of mathematical progression carried the hypnotic persuasive power of an advertising slogan. It was easy to see—"a slight acquaintance with numbers will show," as Malthus said—that even the smallest finite sum growing at the smallest *compound* rate must eventually overwhelm even the largest possible finite sum growing at the highest *simple* rate, so that, whatever the initial situation, there must soon be "standing room only." *Quod erat demonstrandum!*

It did not hurt the Malthusian theory that it justified the resistance of the upper classes to all efforts to reform existing social and political institutions: for if poverty had its roots in the unequal race between population and subsistence, only the working class itself, by practicing prudential restraint, could improve its own conditions. Even the working-class newspapers of the day accepted the desirability of prudential restraint and condemned birth control devices. The Malthusian theory of population was widely appealing: it neatly explained the existence of poverty; it exposed the visionary panaceas of reformers; it enabled everyone to pontificate on questions of public policy; it rationalized the subsistence theory of wages, to which all contemporary economists subscribed; lastly, it underlay Ricardo's preoccupation with the land-using bias of economic progress, and Ricardo was the foremost economist of the day. Any one of these factors would have been enough to make a theory influential. Put together, they fully account for Malthus' astonishing success, a success that has few parallels in the history of ideas.

Despite all the attractive features of the Malthusian theory, it is doubtful, however, whether it would have received so wide a hearing if there had not also been a population explosion in the last two decades of the eighteenth century. Strangely enough, when Malthus published the first edition

of the *Essay* in 1798, he shared the general belief of his day that the population of England had actually increased little in the eighteenth century. The census of 1801 showed how wrong everyone had been, and later generations credited Malthus with prophetic foresight in warning of the dangers of overpopulation as early as 1798. But, in fact, Malthus made no effort, nor was it his intention, to explain the unprecedented population explosion, even in the later versions of the *Essay*. Furthermore, it is evident that he did not provide the tools for such an explanation. The Malthusian theory emphasizes birth and marriage rates, whereas the population explosion of the 1780s was a more complicated phenomenon of rising birth rates in new factory districts and falling death rates in rural areas and congested towns. Unfortunately, the demographic data of the period, based as they are on defective registration of baptisms and burials, are so unreliable that modern authorities are still not agreed on whether the industrial revolution largely created its own labor force by a demand pull on births or whether improved sanitation, nutrition, and housing produced a supply push through a fall in the death rate. The fact remains, however, that Malthus makes a poor guide to the causes of the population explosion that gave such prominence to his views.

Permanent influence. Malthus' magisterial influence on public opinion lasted until the last decades of the nineteenth century. By that time, the record of sustained economic growth, the rise in the standard of living, and the decline in fertility in Western countries made disparagement of the Malthusian doctrine as common as praise had been before. Every schoolboy at the turn of the twentieth century could prove that Malthus had gone wrong by underestimating both the potentialities of technical progress and the possibility of family limitation by birth control devices. As far as it goes, of course, this is a perfectly valid refutation of the Malthusian theory, but it is so obvious now that it is hardly worth stating. One can make a much stronger case against Malthus.

The Malthusian theory of population is a perfect example of metaphysics masquerading as science. So long as we hold with Malthus that birth control is morally reprehensible, the history of population growth in the last two centuries proves him right: nothing has stemmed the tide of human numbers but "misery" and "vice." If, on the other hand, we consider birth control morally defensible, Malthus is vindicated again: "moral restraint" in the larger sense of the phrase is one of the checks that has limited the tendency of population to outstrip the

food supply. The Malthusian theory cannot be refuted because it can be applied to any actual or any conceivable population change: it purports to say something about the real world, and what it says must be true by definition of its own terms.

By the 1920s, the Malthusian theory had lost almost all of its earlier prestige. Indeed, the Malthusian specter of overpopulation had given way to the Keynesian specter of underpopulation. But since World War II, the problem of underdeveloped countries has brought Malthus back into favor. Most underdeveloped countries today have the worst of both worlds: the typical high birth rates of agrarian economies and the typical low death rates of urbanized industrialized economies. Economic development will in time cure these difficulties, as they were cured in industrial Europe, but for the next few generations these countries face the alternative of the Malthusian checks of famine and disease or voluntary family limitation in opposition to prevailing religious mores. The name of Malthus is still bandied about in debates on population policies in Asia, Africa, and Latin America, although it is difficult to believe that the Malthusian theory has much relevance to the discussion of modern population problems. It sheds no light on the causes of declining fertility in developing societies; it tells us little about the demographic relationship between fertility and mortality; it is silent on the economic and social consequences of changes in the age distribution of a population; and it is of no help in framing policies for areas of heavy population pressure. Be that as it may, there is no doubt that the revival of interest in the Malthusian doctrine in our own day makes it one of the longest-lived social theories of all times. And, popular interest apart, demographers can never ignore him or forget him, for, with all his errors, Malthus put the problem of population growth on the map.

MAN

See ANTHROPOLOGY; EVOLUTION; RACE.

MAN, HENDRIK (HENRI) DE

Hendrik (Henri) de Man (1885–1953), a Flemish-born socialist militant, was led by his long and disheartening experience with the stultified proletariat and bureaucratized socialist movements of Belgium, Germany, and England to question the doctrinal and pragmatic adequacy of that radical Marxism to which he had early subscribed. His

searing experience during World War I of man's capacity for self-sacrifice and of the role of national identity precipitated a major reformulation of socialist ideology, presented in his works *Psychology of Socialism* (1926) and *Die sozialistische Idee* (1933). This critique from the left could not be dismissed as mere bourgeois propaganda and, moreover, answered to the radical discontent with socialist practice reflected at that time in the defection of militants to the communist movement.

De Man's essential argument concerned the inadequacy of Marxist theory to account for contemporary trends within the socialist movement—above all, the unacknowledged collapse of chiliastic expectations that a socialist society would be ensured by means of the proletarian conquest of power. In political reality, the widening split between socialist practice and theory was leading to the covert sanctioning of reformist accommodation to the Western bourgeois order, a process that was merely veiled by the increasingly unrealistic revolutionary ideology. At the same time, the Russian experience demonstrated that orthodox Marxism could engender a tyrannical and Philistine sham egalitarianism.

The basic cause of the discrepancy between theory and practice was, de Man argued, the utilitarian explanation of behavior, which Marxism had inherited from classical economics. In interpreting all significant human action as the product of the maximization of advantages, "scientific socialism" had misinterpreted its own nature. This was strikingly demonstrated by its failure to explain such an anomaly as the absence of a class-conscious socialist movement in America and by the interpretation of the European movement as a response to economic conditions per se rather than to the conjunction of these conditions with invidious social distinctions.

De Man believed that if the autonomous role of values were recognized, it would also become evident that the development of a socialist society involved not only revolutionizing outward relations to the means of production but also infusing the work role itself with socialist values. This insight informed de Man's pioneer study in industrial sociology, *Joy in Work* (1927). Further, he held that an ideology that justified socialism in terms of values rather than class interests would more clearly establish the manifold goals of the socialist movement and would facilitate its coming to political power by furnishing a cogent basis for rallying nonproletarian support.

These ideological considerations received concrete political expression in the form of the *plan du*

travail with which de Man returned to Belgium in 1933 from the University of Frankfurt, shaken by the overthrow of that *Sozialdemokratie* in which he had invested his greatest hope of reformation. The new plan of action, which defined a minimal program necessary to resuscitate the economy—essentially a substantial public works program and public control of the principal credit institutions—and which called for political support from all segments of the population suffering from the hegemony of finance capitalism, revived the *élan* of the Belgian socialist party. But with the onset of a financial crisis in 1935 the party, in effect, sacrificed integral *planisme* in order to participate in progressive coalition governments, in which de Man occupied strategic ministerial positions.

In the late 1930s de Man, frustrated by the evanescence of "structural reform" and unsuited by temperament to the compromises of political practice, called for radical revision of parliamentary government in the direction of what he termed authoritarian democracy, capable of sustained and resolute action. He also diverged from his fellow socialists in his fidelity to the appeasement policy: upon the Nazi conquest, he issued a manifesto in which he celebrated the cessation of the ineffective political role of the socialist movement and recommended a rigidly neutralist policy toward the occupying power (1940). Within a year de Man had to acknowledge the bankruptcy of his desperate attempt to construe Nazism in the image of socialism, and he thereupon completely withdrew from public life. He found ultimate refuge in Switzerland and after the war was convicted *in absentia* for treason. Generalizing from the ruin of his life's ambitions, he concluded that the socialist movement could not transcend its capitalist environment; in the general decadence the responsible individual could hope only that it would be possible to preserve the patrimony of the ages despite the convulsions of the historical "zone of catastrophe."

If the political circumstances of the 1930s robbed de Man's ideological reformulation of its force, the folly of the war years guaranteed that none thereafter would speak in his name. Yet post-war developments have moved socialism in the direction he indicated, and perhaps the perspicacity of this sociological socialist is best indicated by his insistence that responsible socialism must make ideological provision for the positive implementation of the rights of man in industrial society.

MANDEVILLE, BERNARD

Bernard Mandeville (1670?-1733), English political satirist, was born in (or near) Rotterdam. He was educated there at the Erasmian School and, at the age of 15, matriculated at the University of Leiden. There his studies included medicine and philosophy. The early influence on Mandeville of mechanistic philosophy—Descartes and Gassendi—was later reinforced by a reading of Hobbes. The fourth generation of a medical family, Mandeville took his M.D. in 1691 and followed his father's specialization in nervous and digestive disorders. By 1699 he had moved this practice to England, settled, and married there. He published a dialogue on his speciality, *A Treatise of the Hypochondriack and Hysterick Diseases* (1711; enlarged in 1730),

but even before this work appeared he had begun a second career as a satirist and wit, an anatomist of individual and social behavior.

Among Mandeville's early poems, translations, and dialogues—all published anonymously—was *The Grumbling Hive: Or, Knaves Turn'd Honest* (1705), a pamphlet describing in verse a thriving, vicious beehive: "Millions endeavouring to supply / Each other's Lust and Vanity" ([1714-1729] 1957, volume 1, p. 18). Each part is vicious, but the whole hive is wealthy and powerful. It is a dissatisfied, grumbling hive until, miraculously reformed, it becomes virtuous, contented, and, consequently, impoverished and depopulated. Since vice is as much a cause of greatness as hunger is of eating, "fools only strive / To make a Great an Honest Hive"; proponents of the Golden Age "must be as free, / For Acorns, as for Honesty" (*ibid.*, volume 1, pp. 36-37). In 1714 Mandeville explained the poem in "An Enquiry Into the Origin of Moral Virtue" and twenty "Remarks," entitling the now substantial work *The Fable of the Bees: Or, Private Vices, Publick Benefits*. In 1723 he expanded the work again, enlarging the "Remarks" and adding "An Essay on Charity and Charity-schools" and "A Search Into the Nature of Society." A second volume, *The Fable of the Bees, Part II* (a series of explanatory dialogues), appeared in 1729. Mandeville reiterated and corrected his views in *An Enquiry Into the Origin of Honour, and the Usefulness of Christianity in War* (1732).

Mandeville's outrageous paradox—"private vices, publick benefits"—involves a series of suggestive explanations. The vices of luxury (unnecessary consumption), pride (vain and fashionable display), greed, envy, and avarice (self-interest in various forms) all contribute to prosperity. To supply the luxury of a scarlet coat requires many manufacturing and trading operations—an extensive division of labor (see [1714] 1957, volume 1, pp. 356-358; volume 2, pp. 142, 284). A nation that restricts the consumption of foreign luxuries to achieve frugality will instead reduce its own prosperity because the countries that export those luxuries will no longer be able to import its own goods (*ibid.*, volume 1, pp. 107-116). Mandeville's descriptions of the economic benefits of vice, crime, and (limited) natural disaster approach the modern concept of a self-regulating economic system (*ibid.*, volume 1, pp. 85-89, 359-364). Among the benefits of the scheme proposed in *A Modest Defence of Publick Stews* is a self-regulating supply of prostitutes (1724, pp. 64-65).

Although his objections to meddling with trade make Mandeville a forerunner of laissez-faire

([1714] 1957, volume 1, pp. 299–300; volume 2, p. 353), he advocated not only that private property be secured, justice be impartially administered, and trade, agriculture, and fishery be promoted but also that the government manage taxes and prohibitions to maintain a favorable balance of trade (*ibid.*, volume 1, pp. 115–117, 197, 248–249). Private vices may be made public benefits through skillful management by a wise politician (*ibid.*, volume 1, p. 169).

Mandeville's argument was annoying because he insisted that vices are not the consequences of social decadence but rather the very motives on which a flourishing, civilized, powerful society depends; simultaneously, he insisted that these vices are obviously incompatible with virtue (or Christianity), which requires a self-denying endeavor to benefit others or to be good (*ibid.*, volume 1, pp. 48–49; volume 2, pp. 16–19, 109–110). Not only is virtue contrary to human instinct; but society is not, as Shaftesbury had argued, based on man's natural sociability. Society is founded on the difficulty men have in gratifying their appetites (self-preservation) and is made possible by their susceptibility to praise (self-love) and their capacity for hypocrisy. Men have been socialized by politicians and moralists who, by flattery, have produced the moral virtues, especially honor and shame, and thus induced men to conform to the fashionable social code, profess virtue, and disguise their passions even though they cannot conquer them. But Mandeville's functional analysis of social institutions does not depend upon the existence of mythical dexterous politicians, for, as he explains, morality, language, government, arts, and sciences—all social institutions—are "the joynt Labour of many Ages" (*ibid.*, volume 2, pp. 128, 238–243, 266–269, 285–290, 318–323; 1732, p. 41).

The *Fable's* vigorous wit and social satire, like the similar mockery of Erasmus and La Rochefoucauld, was intended to encourage men to examine their own motives instead of censuring others. Especially in his *Free Thoughts on Religion* (1720), Mandeville followed Bayle in skeptically arguing for toleration and against priestcraft, in particular clerical politics. He pointed out that most men believe about God what they have been taught from infancy, but few men live according to their professed beliefs. Atheists, whether abstruse philosophers or aristocratic libertines, are few and harmless (1720, pp. 4–6).

Mandeville's *Fable of the Bees* was widely read in the eighteenth century. Berkeley denounced it for libertinism and atheism; Francis Hutcheson objected to its egoistic reduction of morality.

Hutcheson's pupil Adam Smith rejected Mandeville's moral theory but was influenced by the general tendencies of the *Fable* toward laissez-faire economics and the description of the division of labor. Luxury was a widely discussed eighteenth-century problem; Voltaire's treatment of it is derived from the *Fable*. Both Hume and Rousseau mention Mandeville; both are indebted to him.

MANGOLDT, HANS KARL EMIL VON

Hans Karl Emil von Mangoldt (1824–1868), German economist, was born in Dresden. After studying law and political science at the universities of Leipzig and Geneva, he took his doctorate in political science at the University of Tübingen with a dissertation entitled "Über die Aufgabe,

Stellung und Einrichtung der Sparkassen" (1847; "On the Purpose, Position, and Establishment of Savings Banks"). He returned to Dresden after obtaining his doctorate.

It was some years before Mangoldt entered upon an academic career. Between 1847 and 1850 he held a post in the ministry of foreign affairs but had to resign for political reasons. After spending two years in Leipzig studying political economy, he became editor of the *Weimarer Zeitung* in 1852. However, his political convictions again made it necessary for him to resign his position. The publication of his *Lehre vom Unternehmervergewinn* in 1855 won him an appointment as *Privatdozent* of political economy at the University of Göttingen, and in 1858 he was promoted to associate professor. In 1862 he was appointed professor of political science and political economy at the University of Freiburg (Breisgau). Only four years after he moved there he died of a heart attack.

Mangoldt's principal works, *Die Lehre vom Unternehmervergewinn* (1855) and *Grundriss der Volkswirtschaftslehre* (1863), are outstanding works of nineteenth-century German economics. Yet at the time that he wrote, the significance of his contributions was more fully appreciated in England than in Germany. The neglect and even rejection of economic theory that prevailed in Germany after the rise of the historical school diminished the impact of Mangoldt's ideas on economists in German universities, who lacked the well-grounded theoretical tradition of their Anglo-Saxon colleagues.

In England, Mangoldt's theory of international values—a highly original extension of Ricardo's theory of comparative costs—aroused the interest of F. Y. Edgeworth, who discussed it at length in the *Economic Journal* (1894); and his doctrine of entrepreneurial profit was mentioned approvingly by Alfred Marshall in the latter's exposition of his theory of quasi-rent: "It has indeed been shown by a long series of writers, among whom Senior and Mill, Hermann and Mangoldt are conspicuous, that much of what is commonly called profits ought rather to be regarded as belonging to a special class of income derived from 'a differential advantage in producing a commodity'; that is, the possession by one or more persons of facilities for production that are not accessible to all" ([1890] 1961, vol. 2, p. 462). Indeed, Mangoldt was one of the first economists who endeavored to establish entrepreneurial profit as a special category of income alongside wages, interest, and rent.

Mangoldt's theory of prices, as expounded in the first edition of the *Grundriss*, is truly a pioneer achievement of lasting value. With a precision not

attained by any other author prior to 1863, he set forth the static theory of price formation on the assumption of free atomistic competition in supply and demand; the form of his presentation remains valid today. Cournot had employed curves of supply and demand as far back as 1838, but there is no reason to assume that Mangoldt was acquainted with Cournot's work; Edgeworth was probably right when he described Mangoldt as "one of the independent discoverers of the mathematical theory of Demand and Supply" (see 1891–1921, pp. 52–53). Yet Mangoldt went far beyond Cournot, and this is his truly original contribution. He did not confine himself to determining the existence of an equilibrium price but set forth the special features of price formation that arise from various forms of the supply curve and the demand curve and pointed out that there may be several equilibrium prices. He also described the process of transition from disequilibrium to an equilibrium price. Yet Mangoldt's most significant contribution to price theory is, no doubt, the analysis of price formation for the case of joint demands or for the case of joint supplies or for the case of both. Ideas and modes of thought initiated here were not developed further until Alfred Marshall took them up.

Mangoldt's important pioneering achievements were not appreciated in Germany. Although the second edition of the *Grundriss*, edited by F. Kleinwächter in 1871, after Mangoldt's death, appeared without any of the geometrical apparatus of the first edition, the book failed to gain a wider market. Only today do we begin to realize the significance of Mangoldt's contribution as an important link in the chain of great German theoretical achievements of the nineteenth century.

MANIC-DEPRESSIVE DISORDERS

See DEPRESSIVE DISORDERS.

MANNHEIM, KARL

Karl Mannheim (1893-1947), German sociologist, was born in Budapest. He attended school in that city and then studied at the universities of Berlin, Budapest, Paris, and Freiburg before going to the University of Heidelberg, where he habilitated as a *Privatdozent* in 1926. At that time Heidelberg was still the major intellectual center of the German academic world. Alfred Weber, Heinrich Rickert, Marianne Weber, Friedrich Gundolf, Ernst Kantorowicz, and Emil Lederer were among its major personalities. The spirit of Max Weber, who had died in 1920, dominated the atmosphere, and the youthful brilliance of György Lukács in his pre-Marxist period had not been forgotten. Mannheim lived and worked in Heidelberg until he was called to the professorship of sociology at the University of Frankfurt in 1930. He remained at that post until the spring of 1933, when, following the coming to power of the National Socialists, he took refuge in Great Britain. There he was lecturer in sociology at the University of London (London School of Economics) from 1933 to 1945; and from 1945 until his death, he was professor of the sociology and philosophy of education in the Institute of Education at the same university.

Mannheim's work falls into two main phases, which correspond approximately to his German and his British careers. In the first phase the sociology of knowledge—its methodological legitimation, its epistemological implications, and its substantive application—formed his main field of work. In the second phase the study of the structure of modern society came to the fore. In these latter studies he combined macrosociological and microsociological concerns with an explicit interest in social policy.

Sociology of knowledge

Mannheim's early writings expressed his struggle against the inheritance of German idealism. They were attempts to revise its epistemology in an instrumentalist direction and constituted a critique of its conception of intellectual history as an autono-

mously developing sequence of ideas. In this first phase of his work Mannheim was much influenced by the tradition of historicism and by the Marxist model of society; no less fundamental to his thought was his interest, derived from the classics of German sociological thought and from Marxism, in the structure and determinants of agreement and disagreement, of consensus and dissensus.

Mannheim went further than Marx and Tönnies: they saw society split by class conflict and class interest or by mutual distrust; Mannheim thought that the cleavages existed at deeper levels as well. Mannheim saw social cleavages not merely as divergences of interest but as divergences of modes of thought, of the categories in which events are conceived, and even, indeed, of the very criteria of validity. In "Competition as a Cultural Phenomenon" (1929) and *Ideology and Utopia* (1929-1931) he set forth his views on the profundity of the cleavages in styles of thought which had developed in modern times.

The profundity of these cleavages led Mannheim to formulate the distinction between "particular" and "total" conceptions of ideology. He was always concerned with the re-establishment of consensus: believing that the disintegration of the social order had penetrated into the epistemological and ontological spheres, he desired to lay the foundations for a comprehensive "perspective" which would transcend the partial perspectives associated with particular social positions. In *Ideology and Utopia* and in his article "Wissenssoziologie" he sought an epistemological solution (the article is incorporated in the English and American editions). Independently of Durkheim's and Lévy-Bruhl's relativization and "sociologization" of the categories of thought, Mannheim asserted that the fundamental categories are functions of divergent interests, aspirations, and *Weltanschauungen*, which are in turn related to social status, role, and position; he sought a way out in what he called "relationism." He insisted that the truth of a proposition cannot be assessed without regard for the "values and position of the subject . . . and the social content"; he did not take seriously the possibility of autonomous, disinterested, and disciplined intellectual action. The historicist view that each age has its own distinctive problems, views of the world, and conceptions of the good and true; the Marxist view that there are "bourgeois" and "proletarian" truths; and the idea of *Weltanschauung*, developed in the writings of Dilthey and Spranger, all came together in Mannheim's thought in the 1920s.

Mannheim's earliest formulation of relationism, in "On the Interpretations of 'Weltanschauung'" (1923), prefigured the whole concern and intellec-

tual position of his German period. This essay represents an effort to legitimate a mode of understanding intellectual works as manifestations, expressions, or parts of something else. He regarded the *Weltanschauung* of an individual, school, or epoch as the nonrational matrix from which every particular work was an emanation. A major task of the analysis of particular works was, therefore, to discern their "style." According to this approach, style consists of features which a work shares with other works, which each part of a work shares with each other part of the work, and which intellectual works share with nonintellectual manifestations of a *Weltanschauung*. Thus, the problem with which Mannheim was concerned was the subsumption of a particular work under the pattern of other works like it and of the style of the *Weltanschauung* as a whole. Each particular intellectual work was treated—and accounted for—as related to or derived from something else.

Although Mannheim first applied this conception to art history, its implications for the next stage of his thought were patent. In two essays, "The Problem of a Sociology of Knowledge" (1925) and "Ideologische und soziologische Interpretation der geistigen Gebilde" (1926), he advanced to the treatment of moral works, mainly works of political and social philosophy, and to the "sociological approach." Whereas the "ideological" interpretation of intellectual works treated them simply as derivable from other intellectual works which preceded them and as generated by a process internal to the mind, the sociological approach purported to go further. It claimed that intellectual works are generated in response to the needs of the class or group to which their creators belong, as it is confronted with "practical" tasks and challenges to its position by other classes or groups. However much he sought to distinguish his own view from Marxism, he never fully escaped from the Marxist categories of *Unterbau* and *Überbau*.

The question may be asked, Did he really succeed, in this first phase of his work, in freeing himself from the ideological interpretation he tried to transcend? Much of his subsequent sociological analysis of political and cultural beliefs, not least that in his major substantive work, "Conservative Thought" (1927), consisted in relating particular beliefs to more general patterns of belief or *Weltanschauungen*. His work became sociological through scattered assertions that particular views are correlated with particular value orientations, characteristic of particular roles or statuses—for example, membership in particular social classes or the practice of particular occupations or styles of life. In this period he attempted fewer correlations

with social structural variables than with the culture or value orientations of classes or occupational strata. His "sociological" interpretations of political and social beliefs remained ideological. Nonetheless, the specification of the social group which possesses a particular culture or *Weltanschauung* did represent a genuinely sociological extension of the ideological approach, rather than its replacement or negation.

The sociological variables Mannheim used in this phase of his career were largely derived from Marxism, e.g., "declining classes," "ascendant classes," "threatened classes," "newly self-conscious classes," etc., although he also cited generations, sects, and parties as the structural bearers of different *Weltanschauungen*. In *Ideology and Utopia* he asserted, for example, that "uprooted" and "unintegrated" revolutionary groups think intuitively and lay little or no stress on historical development; that conservative groups think morphologically; that liberal-humanitarian strata stress the openness of the future and the progressive realization of ethical values; and that oppressed strata, which are chiliastic, expect immediate and sharply disjunctive changes.

The correlations were at best no more than correlations. Mannheim avoided the task of causal imputation and of a differentiated analysis of the process or mechanism through which ideas and social position are connected. In the main he committed himself to nothing more than the assertion that thought is "existentially connected" (*seinsverbunden*) with social position. His work was characterized by insights of great penetration, both into the interconnections between diverse elements in a given *Weltanschauung* and also, if more rarely, into the correlations of these elements with "positions" in society.

The contradictory combination of a persistent idealism with the Marxist negation of idealism by "standing it on its head" remained basic in Mannheim's thought throughout his German period. It was a contradiction which he did not overcome and of which he was unaware. His continuous insistence that the "internalist" (ideological) view is wrong and his failure to recognize how much of it he himself retained led to his failure to perceive the partial autonomy of intellectual traditions and the institutional structure in which autonomous intellectual activity is effectuated. By constantly stressing that intellectual activities are responses to current practical-political situations, which are "nonintellectual," he was precluded from a sociological analysis of the institutional structures of intellectual activity, which make possible the continuity of intellectual traditions. (His one effort to

study the social processes that are immanent in intellectual continuity and change, "The Problem of Generations" [1928], remained very general and vague and was never assimilated into his sociology of knowledge.)

There were other reasons why Mannheim's sociology of knowledge failed. What he meant by "knowledge" was largely normative and metaphysical beliefs, ideas about the nature and right organization of society, and interpretations of history. He never came to grips with the natural sciences, that is, with science as that term is understood in English-speaking countries. Scientific knowledge as a body of systematically verified beliefs remained at the margin of his interests. The influence of science and of scientific, research-based technology on social structure passed unnoticed before him. This omission made it easier for him to neglect the element of continuity and the processes of internally instigated innovation within an intellectual pattern. His denial that there is anything like a "self-contained intellect which evolves by and from itself" and his equal insistence that every change in a pattern of thought corresponds to "a change in the position of the group" required that intellectual interest and criteria of truth other than the successful mastery of life situations also be denied.

In the three years between the publication of *Ideology and Utopia* and his departure from Germany, Mannheim's transition from the sociology of knowledge to the macrosociological and microsociological study of social structure began to become visible. Much influenced by Max Weber's ideas about bureaucracy, he wrote an essay, "Über das Wesen und die Bedeutung des wirtschaftlichen Erfolgsstrebens" (1930), in which he analyzed the psychological correlates of the bureaucratic career and the bureaucratization of modern society and adumbrated his later interest in a pragmatic educational policy. His interest in personality and culture and in the "planning of personality" also appeared here for the first time. He also wrote a book on the intelligentsia, which was unpublished in his lifetime. (It was published posthumously in 1956, as *Essays on the Sociology of Culture*.) In the final section of that book, entitled "The Democratization of Culture," he presented an original analysis of the postulates of the democratic outlook, setting forth for the first time his later more fully developed views about fundamental democratization and the deterioration of the rationality and solidarity of elites.

The structure of modern society

After Mannheim went to England, he ceased almost entirely to study doctrinal beliefs and their

social correlates. His epistemological interests, which had foundered in inconclusiveness, were largely discontinued. (For example, his distinction, in *Man and Society in an Age of Reconstruction* [1935], of three modes of thought—thought at the level of discovery, at the level of invention, and at the level of planning—avoided all questions of epistemological validity.) Nonetheless, certain earlier themes continued to preoccupy him in this second stage of his career; dissensus, the conflict of classes, the disagreements of doctrines, and the irreconcilability of political movements still engaged his mind, although the particular contexts changed in which these phenomena were seen. While in his first phase his attention was preponderantly directed to the reconciliation of contending and antithetical interpretations of events and criteria of truth, the main aim of the macrosociology of his second period was the delineation of the contemporary dissensus, the disclosure of its causes, and the discovery of the means of its displacement by a new consensus.

Another line of continuity may be seen in his attitude toward sociology. Although in his second phase he came much closer to the scientific aspirations of empirical sociology, he never fully resigned himself to them. He became more sympathetic to the largely ahistorical, sociological, and social-psychological research of the period, but he never ceased to insist on the necessity of a "dynamic" and "historical" sociology. The natural-science model of knowledge remained alien to him and was never integrated into his thought.

In both periods he looked upon sociology as a potential cure for the ills of society. Just as the sociology of knowledge had been intended to emancipate intellectuals from extreme partisanship and from particularistic perspectives ([1929–1931] 1954, pp. 97–104), so a sociologically oriented education and sociologically oriented planning became the means, in his second phase, of overcoming dissensus and of avoiding the dangers of totalitarianism. His historicism led him to underemphasize the elements of identity between various societies, and he therefore believed that modern mass society is afflicted with a degree of dissensus such as no other society had ever suffered. But instead of focusing his attention on the dissensus of the intellectuals, he now stressed the dissensus of social strata and political groups.

Mannheim added some variants of his own to the German sociological tradition which derived from Tönnies and Simmel and which emphasized the disintegration of modern urban society. Unlike his predecessors, who characterized bourgeois society as uniform throughout its history, Mannheim

distinguished between the stages of minority democracy and mass democracy. Several elements, not previously considered in the older diagnosis of the perpetual crisis resulting from unbridled conflicts of individual and collective desires, were added by him: the concentration of authority, the bureaucratization of work, "functional rationalization," increased integration ("increasing interdependence"), and "fundamental democratization." The concomitance of these major processes resulted in the democratization of access to positions within elites. Through these processes individuals who lacked practical and experienced judgment moved into the political elites at the very time that more and more of social life had become dependent on the decisions of these elites.

Mannheim stressed the intensification of demands which accompanied the democratization of political participation and the consequent increase in the frequency of unrealistic and unfulfillable demands. Yet the first years of his sojourn in Great Britain changed the accent of his thought. His outlook became more optimistic and more concrete. The increased optimism was manifested in his effort to promulgate a pattern of democratic planning. The enhanced concreteness arose in part from his increased interest in empirical sociological and social-psychological research. It was also related to the much greater matter-of-factness of discussions of social and political problems in Great Britain, where political differences were not invariably reduced to metaphysical and *weltanschauliche* differences. He became more sympathetic to psychoanalysis and better acquainted with it. He also became increasingly interested in educational techniques—that is, the possibility of transforming conduct through scientifically based educational techniques. This interest, encouraged by Sir Fred Clarke, the director of the University of London Institute of Education, brought him into a greater intimacy with the practical problems of education. His dislike of the prototype of the generally educated man espoused by German idealism had already, in his German period, caused him to reach out toward more practical types of education, which would be concerned with fitting individuals for differentiated social roles. His growing interest in planning strengthened his interest in education as preparation for participation in a democratic consensus.

His membership in an unusual group called the Moot, which met quarterly and which included Joseph Oldham, long active in Church of England affairs and social reform; Alec Vidler, a notable Anglican theologian and historian, then dean of Windsor Chapel; T. S. Eliot; J. Middleton Murry;

and other literary and academic men, civil servants and theologians, made him more sensitive to religious belief and its possible role in the planned democracy of the future than he had ever been before. It was to this group that he presented a long paper, "Towards a New Social Philosophy: A Challenge to Christian Thinkers by a Sociologist" (1943). Mannheim argued that *laissez-faire* has exhausted its possibilities; as a result of fundamental democratization and the process of functional rationalization, the free play of forces in the economy has lost its powers of self-equilibration. Man's capacity for autonomous and responsible individual judgment has weakened at the very time that greater demands for such judgment are being placed on him. The irrationality generated by these two processes has increased the danger of totalitarianism. The "primordial images" which have directed the life experiences of men through the ages have vanished, and nothing has taken their place. Conduct, in consequence, "falls to pieces," and only "disconnected fragments of unintegrated behaviour patterns" remain.

In the final product of his constructive imagination, *Freedom, Power, and Democratic Planning* (1950), Mannheim defined the principal task as the creation of a society-wide "spontaneous" consensus, which would permit planning to be carried out effectively. In Germany he had shared many of the general views of democratic socialism, and in the 1930s he came to accept the inevitability and desirability of planning. To prevent planning from becoming totalitarian, self-restraint in collective demands and confinement of popular participation in the exercise of power to specific occasions were necessary. The indispensable condition for such restraint and limitation was consensus, and the two paths to consensus were, first, pedagogy, and, second, a readiness to accept and even to arouse religious sensibility and the moral attitudes called forth by religious experience. He saw the function of religion as helping man to restrain himself through spontaneously experienced moral norms and therewith to stabilize a social framework which would permit a modicum of freedom in a society that had to be planned in order to exist. Society in its latest phase needed a spiritual purpose, to avoid having a purpose imposed on it by a totalitarian elite. Thus, it became necessary to plan religion—not by prescribing a theology, but by the planned provision of institutional settings in which religious experience could flourish.

Mannheim's influence

Although he was an extraordinarily stimulating teacher, Mannheim had few intellectual descend-

ants: his Frankfurt students were scattered and their incipient careers broken; at the London School of Economics, students interested in empirical research found him insufficiently at home in the then prevailing techniques, and there were very few equipped to do the kind of historical and macrosociological work that was Mannheim's forte. During World War II the teaching of sociology ceased in England, and Mannheim was thereby deprived of the opportunity to influence the new generation of sociologists. In Germany the long suspension of social scientific work resulted in an attrition of the culture required to sustain Mannheim's kind of sociology, and when social scientific work was resumed after the war, the older tradition had been lost and Mannheim's prewar macrosociological writings did not appear relevant to current interests.

The sociology of knowledge as practiced by Mannheim has found no succession. Its only manifestations are Ernst Kohn Bramstedt's dissertation, *Aristocracy and Middle-classes in Germany* (1937), Hans Gerth's "Die sozialgeschichtliche Lage der bürgerlichen Intelligenz um die Wende des 18. Jahrhunderts" (1935), and Hans Speier's "Die Geschichtsphilosophie Lassalle's" (1929). Much work has been done since World War II which may be said to fall within the jurisdiction of the sociology of knowledge broadly conceived, yet very little of it bears the impress of Mannheim's thought.

More recent works like Thomas S. Kuhn's *Structure of Scientific Revolutions* (1962) and Michael Polanyi's *Personal Knowledge* (1958), which have carried very far the systematic analysis of patterns of thought and their modes of change, owe nothing to Mannheim's analyses of *Weltanschauungen*. Similarly, Mircea Eliade and Claude Lévi-Strauss, in work on the fundamental categories of thought, owe much to Jung, Durkheim, and Mauss; they owe practically nothing to Mannheim. Latent-structure analysis, which was developed by Paul F. Lazarsfeld and others for the analysis of attitude-survey data and which offers great possibilities of development for the analysis of the structure of beliefs, is also independent of Mannheim's influence.

The situation is somewhat different with regard to the study of ideologies: there can be little doubt that the prominent place which this kind of work is now beginning to occupy in sociological analysis owes something to the fact that Mannheim brought the term "ideology" to the attention of sociologists. His influence in this area is a product less of anything specific he said about the problems of ideology than of the fact that he dwelt on them long and seriously. Similarly, the study of the political and social role of intellectuals and of the institutional systems of intellectual life, as carried on by

Theodor Geiger, Robert K. Merton, Joseph Ben-David, Talcott Parsons, Helmuth Plessner, Martin Trow, Lewis Coser, A. H. Halsey, and others, owes some of its impetus to Mannheim's concern with these subjects.

Mannheim's macrosociological views of contemporary large-scale society have had a more receptive audience and a more enduring influence. They were in harmony with an already established tradition in the analysis of modern urban society, and their appearance coincided with the emergence of the influence on sociology of Marxism and of Max Weber's writings on bureaucracy and capitalism. Also, they appeared at a time of troubled interest in the causes of the breakdown of liberal societies and the emergence of populist totalitarian regimes and movements. Mannheim's very term "mass society" focused attention on certain unique features of modern large-scale societies, and his emphasis on the significance of bureaucratization and democratization in government, industry, commerce, and culture created one of the major themes of contemporary sociological thought.

Mannheim's "morphological" approach, derived partly from German historicism, partly from Marxism, and partly from Weber's broad categories and comparative studies, made him one of the first proponents of the macrosociological approach in the world of English-language sociology. Here again, it was his inclination to think of society as a whole, rather than his specific hypotheses, which led to macrosociology. He was vague in his formulations, and there is a tantalizing ambiguity in nearly everything he wrote. Yet, he dealt with very important subjects. The adage which asserts that the mistakes of a distinguished mind are more interesting than the truths of a mediocre one was true of Mannheim. He had in large measure the rare gift of touching on vital and enigmatic things.

MANORIAL ECONOMY

The word *manoir* was used in Normandy in the eleventh century to designate the residence of a lord, the point of concentration of his economic and social power, and the place where the products of his lands were collected and where his men performed the services they owed him. In 1086, when Norman clerks drew up the inventory known as the *Domesday Book* for William the Conqueror, they used the word *manoir* as the key term in their descriptions of English estates. The word became part of the vocabulary of England. The expression "manorial economy" thus signifies, for Anglo-Saxon historians, a certain mode of economic organization of men and the land that developed during the feudal period. Continental historians usually employ the term "seigniorial economy."

Earliest manifestations. The first clear image of the manorial system appears from documents drawn up in the ninth century in northern France, western Germany, and Lombardy describing the landed estates of large monasteries and the way in which they were managed. The French scholar Benjamin Guérard published the oldest and most complete of these inventories, which was drawn up before 829 for the monastery of Saint-Germain-des-Prés in Paris. He made the first analysis of manorial economy at that period; the work of subsequent medievalists has added precision to his analysis.

These immense monastic estates were divided for management purposes into large units known as *villae*; their centers (*curtis*) corresponded exactly to the *manoir* in the Anglo-Norman vocabulary of the eleventh century. A more or less compact assemblage of cultivated and uncultivated land, covering hundreds and often thousands of hectares, was attached to the residence of the lord. This enormous landed estate was divided into two portions, each having entirely different economic functions.

The larger part, which comprised all the woods and pastures, most of the meadows and vineyards, and large tracts of arable land, formed the domain proper (*terra indominicata*). The master of the *villa* kept direct operation of this in his own hands and received all its produce.

The rest of the land was broken up into a number of operating units of much smaller size. Each of these, containing only a few hectares of plowland and sometimes a bit of meadow and vineyard, was attached to the lot where the family of the peasant lived (*mansus*). Each family of workers managed this farm and took what it produced, in exchange for certain obligations to the lord. This was a holding. The oldest inventories make a distinction between two types of *mansi*: one called free, the other servile. There were also two large legal categories among the peasant population: the freemen and the slaves. However, no perfect agreement existed between the status of the tenure and that of the peasants who operated it: some freeholdings were occupied by households of slaves and vice versa.

This division of the lord's land into two parts, the domain and the individual holdings, was in response to operating requirements. The central problem of management was a problem of manpower. The very low level of farming technique and the wretched inefficiency of farm tools made it necessary to employ a large number of laborers to make the fields and vineyards sufficiently productive. But the rural regions of Europe were very sparsely inhabited in the ninth century and there was insufficient money in circulation to permit regular use of wage labor. On the other hand, the reduction in traffic in slaves had made it impossible, by the ninth century, to base the operation of great aristocratic domains on the employment of human chattels, as had been done in previous epochs.

A set of domestic slaves was still maintained at the lord's residence at the center of the *villa*, but they were too few to farm the vast cultivated fields of the reservation at the time of major operations: haymaking, harvesting, vintage, ditching and fencing, cultivating the vineyards and, above all, plowing. Moreover, this team of domestics had to be re-formed periodically. The chief function of the holdings was to ensure periodical renewal of this group of domestics and provide it with supplementary unpaid labor services. The tenures known as servile were probably originally set up by the lord in order that some of his slaves might lead a family life on each such *mansus*. This separate settlement had two advantages.

The slave family had to get its food from its own

holding. The lord was thus relieved of its maintenance. To be sure, this meant the loss of a part of the productive power of the family, but only a part. The tenant slaves continued to work for him without pay. The women were employed in the domestic workshops of the *villa* and produced pieces of cloth at home. The head of the family had to do any tasks given him during three days a week. The first function of the tenure was to provide the master with unpaid, half-time domestics.

Further, the married slaves, established by pairs in family homes, begot children and raised them until they were of an age to work. From these children the lord recruited the servants for full-time service in his house. Thus, the existence of servile tenures promoted the operation of a type of slave economy in an economic and social *ambiance* in which the slave markets were no longer regularly supplied.

As for the tenures known as free, whether they too had been set up by the lord on his own lands or were peasant farms that had once been independent and had been annexed to the *villa* in one way or another, they were generally more extensive than the servile tenures, for the peasant families holding them had a larger proportion of their time available for working their farms and usually kept work animals. The economic function of these freeholdings was a different one. To some extent they provided income, delivering a portion of their produce to the lord in the form of dues—in kind or in money. Their main contribution to the economy of the *villa*, however, was likewise labor. This took two forms: (1) a piece of land from the domain, assigned each year to each holding, had to be cultivated and its entire produce turned in; (2) at fixed times, for a certain number of days, the tenants, with their teams, had to be at the service of the lord and help the household servants in the work of plowing and cartage.

The system described above seems to have been fairly widespread in the ninth century in the regions between the Loire and the Rhine, and in the Po Valley. There it represented a developed form of the great aristocratic estates of the Roman era. From that time on, it seems to have spread gradually in the Germanic regions and in England. It was, in fact, perfectly adapted to a social structure in which slavery was in the process of dissolution but in which a sharp distinction was maintained in the peasant world between the free and the unfree, and in which a strong aristocracy, religious or secular, held huge tracts of land and completely dominated those who labored on the land. The economy was certainly not entirely closed (the

existence of regular dues in money proves that the tenures, as well as the great estates, were normally engaged on the market), but labor productivity was low, population sparse, and the circulation of money very slow. The manorial system, whose basic nexus was the association of the holdings to the work of the domain, made possible the operation of the great grain-producing estates on which the power of the aristocracy rested.

Development under feudalism. Between the tenth and thirteenth centuries, in the rural regions of western Europe, the political power of the landholding aristocracy was strengthened and the old forms of slavery disappeared. The peasants were still divided into two legal categories: (1) the "free" peasants, subject only to the territorial lord's powers of justice and police; and (2) the personal dependents—serfs, *hommes de corps*, *Leibeigene*, villeins—hereditarily attached to a private master. The most significant changes took place in production. Great progress in rural techniques brought about a sharp improvement in the yield of human labor, and, as a result, a continual growth of population and acceleration in exchange and in the circulation of money. The manorial economy adapted to this evolution in the environment.

England. The new forms of the manorial economy appear most clearly in thirteenth-century England. An abundance of documents, well exploited by economic historians, gives us the following picture of the structure of the manor on the landed estates of the great English religious foundations.

The heart of the manor was the domain, a large unit whose production was to a great extent intended for sale, for at that time there were large markets for grain and wool. The peasant holdings ranged around the domain. Some of them were free, and their obligations consisted almost exclusively of dues. The others, which were closely associated in the work of the domain, fell into two groups. (1) Some, granted to men known as *bordarii*, were too small to provide full sustenance for the family that occupied them. Their holders were required to give one or more days of unpaid labor on the domain of the manor; additional days were worked for payment. (2) The tenures granted to *villani*, on the other hand, corresponded in size to the labor power and needs of a peasant household having a plow and team. Their obligations were much heavier. There was a multiplicity of dues which transferred a large portion of the produce of the land to the seignorial house. Above all, there were various kinds of *corvée*, or forced labor: the tenant and his livestock were summoned to perform both definite tasks and what was called

"week work"—the obligation to go to work on the domain a certain number of days each week. On some manors, during the heaviest work of harvesting and haymaking, this duty could extend to all the people living on the holding and to every working day. In addition, in the thirteenth century *villani* and *bordarii* were held to have no liberty. Accordingly, they were excluded from the jurisdiction of the public courts and subject to the private justice of the manor. They paid a number of personal taxes, by means of which the lord appropriated a part of the money they earned.

On these manors, therefore, the association for work between the domain and the individual holdings remained unbroken. On the contrary, during the thirteenth century the link seems to have become tighter: the managers of the great monastic estates, eager to increase production on the domains in order to have more to sell, were stricter in exacting the *corvée* and tried to extend such work. However, the *corvée* never was sufficient to get the work of the domain done. Part, often the major part, of the labor was done by a set of full-time servants and by workers for wages. The *bordarii* were regularly hired on the days they were not required to do unpaid work, and so were the poor peasants of the village, who were looking for supplementary resources. The growth of this rural proletariat in the thirteenth century favored recourse to paid labor; it kept the level of wages very low while the price of food rose, thus increasing the profits of the large estates.

It should be added that the manorial organization described in the ecclesiastical documents did not by any means characterize all seignorial lands. On most English manors the part played by statute laborers in working the domain was very slight or nonexistent; servants and wage laborers constituted the entire labor force.

The Continent. On the Continent—in France, the Low Countries, Germany, and Italy—the statute labor required from tenants diminished during the eleventh and twelfth centuries. By the thirteenth century, it had very often disappeared completely or was only two, three, or four days a year. Dues, collected in money for the most part, had taken its place. The old tenures, many of which had broken up and disintegrated, thus yielded only money income. The very large number of new holdings set up on the vast expanses of newly cultivated land had for the most part been exempted from *corvées* since their inception. Further, changes in the price level had in effect reduced the money dues, the most common obligation. By the thirteenth century, the obligations of the tenures had become

trifling. Finally, emancipations had greatly reduced the number and cost of personal dependents.

But although the old manorial system was no longer very profitable to the aristocracy, they gained by other means. By taxes on inheritances and sales of tenures, by tithes on harvests, by tallage (*taille*, a periodical tapping of the capital in chattels of the peasant households), the lords took virtually all the money earned by a more numerous and more productive peasantry. Further, great investment operations—extensions of vineyards and cattle raising and, in Italy, of the *coltura promiscua*—introduced contracts of a new type binding the rural laborers to the lords. The latter contributed the land and the capital but kept the greater part of the profits.

However, the lords had not turned into mere passive receivers of income from the land. The almost complete disappearance of forced labor had not diminished the economic importance of the management of their domains, whose value had been considerably increased by the advances in rural production. But this large-scale seigniorial farming was now based on the use of domestics and hired labor; it was furthered by the opening of the market for agricultural products and by the growth of the rural proletariat.

Final forms of the manorial economy. The last parts of the framework of manorial organizations were gradually destroyed in Europe during the thirteenth and fourteenth centuries by the extension of leaseholding (contracts of *fermage*). Under this system certain economic powers were ceded for short periods to an intermediary in exchange for payments fixed in advance. It was employed very early for the collection of certain seigniorial rents. On the Continent it was employed by the greatest lords in the operation of their domains from the end of the twelfth century on. For an annual payment the lands of the domain, all the means for cultivating them, and, in particular, what was left of statute labor, were granted for some years, under certain guarantees, to a farming entrepreneur—the community of the peasants of the village, the former bailiff, a bourgeois capitalist, or even an ordinary peasant who had enough ability to take over the operation of all the great domain. Use of this procedure spread very widely during the fourteenth century and soon got to England.

At that time, the dominant tendencies in rural economy were reversed almost everywhere. Rural population was rapidly decreasing. The resultant rise in agricultural wages, coupled with the fall in grain prices, tolled the knell of the large-scale agricultural operation based on wage labor. From

that time on, the extension of leaseholdings was accompanied by division of the great domains into small holdings. Leaseholds and farm contracts calling for payment in kind (*métayage*) were for much smaller tracts, corresponding to the means of production of a family helped by a few domestics. At the same time, political and social disorders did away with almost all survivals of personal servitude. In eastern Germany, however, certain political conditions, producing a re-formation of serfdom, intervened to promote the rise of large estates based on the *corvée*, namely, the *Gutsherrschaften*, the longest-lasting form of manorial economy.

MARETT, ROBERT RANULPH

Robert Ranulph Marett (1866-1943) was one of a number of classically trained scholars in England (Frazer, Andrew Lang, and Myres were others) who at the end of the nineteenth century were attracted to the then developing subject of anthropology. Marett's own interest in anthropology was originally stimulated by his preparations for the Oxford University Green moral philosophy prize, which in 1893 was to be given to an essay on the ethics of savage races. At the time a tutor in philos-

ophy at Exeter College, Marett won the prize, and so came into the orbit of E. B. Tylor. Marett was to spend almost his entire academic life at Oxford (from 1928 until his death he occupied the post of rector of Exeter College).

He remained essentially an "armchair" anthropologist, although he conducted some archeological excavations on his native island of Jersey. His major interests lay in the field of primitive religion. His theories of a "preanimistic" stage of religion were a development of Tylor's concept of "animism," but he insisted also upon the psychological component of religious belief. Unlike the heavy, comparative treatises of many of his contemporaries, most of Marett's books were initially lectures and addresses. He excelled in the nicely illustrated argument which examines in brief compass a new idea, approach, or observation. Marett's initial reputation was acquired through one such paper, delivered to the British Association for the Advancement of Science in 1899, "Pre-animistic Religion." Coming at a time when the psychological component of behavior was receiving growing recognition, the central idea—that a diffuse religious feeling probably preceded Tylor's postulated creed of "belief in spiritual beings"—was accepted by a number of English and German scholars and received the distinction of a lengthy discussion in Wundt's *Völkerpsychologie*, where it was translated as "der Marettsche Präanimismus." The paper was included in Marett's first collection of essays, *The Threshold of Religion* (1900), which contains many of his key and most original ideas.

Anthropology, a popular general account reprinted many times in the following decades, was published in 1912, and a second collection of essays and addresses, *Psychology and Folk-lore*, in 1920. Marett was invited to give the Gifford lectures at St. Andrew's University in 1931/1932, and these were published in two volumes—the first, *Faith, Hope and Charity in Primitive Religion* (1932), dealing with religious sentiment in primitive societies, and the second, *Sacraments of Simple Folk* (1933), with primitive rituals. A final collection of essays, *Head, Heart & Hands in Human Evolution*, appeared in 1935, followed the next year by a biography of Tylor.

Marett viewed anthropology as a broad, coordinated study centrally concerned with "man in evolution." He stated many times that anthropology is based on Darwinian theory, but his was a humanized Darwinism, which insisted upon the unity of human nature that underlies the diversity of behavior: "Darwinism is the touch of nature that makes the whole world kin" (1912, p. 11). In view of the importance which is generally ascribed to

Tylor's introduction into anthropology of the concept of "culture," it is interesting to observe that Marett, Tylor's pupil and great admirer, did not begin to make any distinctive use of this concept before he wrote the papers published in *Psychology and Folk-lore* (1920), by which time it was also being developed by other writers, notably in the United States. The methodologically more diffuse concept "custom" was, for Marett, more important; he viewed behavior in primitive society as essentially "custom-bound," and primitive religion as "mobbish."

Marett criticized Tylor's and Frazer's theories concerning religion and magic for their "intellectualism" and pointed out the absurdity of regarding the "savage" as a kind of "primitive philosopher"; yet, in his own theories he perhaps did little more than substitute notions of primitive faith or religious "feeling" for their notions of primitive creed or their postulated theories about nature. For Marett, the original "stuff" of religion was "supernaturalism," a matter of emotion rather than of intellect; "that basic feeling of Awe, which drives a man ere he can think or theorise upon it, into personal relations with the Supernatural" ([1900] 1929, p. 15). Both magic and religion spring from this original, undifferentiated category of experience (which he called "magico-religious"), the former in practices antithetical to the common good, the latter in practices or beliefs in harmony with it. The concepts of taboo and mana gave Marett ethnographic evidence for such elemental apprehension of the supernatural, "mana" referring to it in a positive mode, "taboo" in a negative mode. This taboo-mana formula, delineating a belief in impersonal forces, Marett adopted for his own minimum definition of religion. He also referred to this wider category of belief by the term "animatism," in order to distinguish it from Tylor's "animism," defining it as "the attribution of life and personality to things, but not of a separate apparitional soul" (British Association . . . 1912, p. 262).

The teaching of anthropology in Oxford had started in 1884, with Tylor's appointment as reader, but he had extremely few pupils, and it was not until 1905, with the setting up of a committee for anthropology and the inauguration of a diploma in anthropology (in which Marett was actively concerned), that the subject obtained wider recognition in the university and a regular flow of students began. Marett held the post of reader in social anthropology from 1908 until 1934, when a chair was created, which Marett occupied for one year, until Radcliffe-Brown, who had already been appointed, was able to take up his duties. Despite his own lack of field experience, Marett held that the

teaching of anthropology should be directed toward field work; the teaching of prospective colonial administrators was started at Oxford shortly after the diploma course was inaugurated, and a number of the students (including A. C. Hollis, R. S. Rat-tray and C. K. Meek) later made important contri-butions to anthropology while holding appoint-ments in the colonial service.

MARKET ANALYSIS

Market analysis is concerned with predicting the size and location of markets as measured by sales. The term is sometimes used as a synonym for

"market research," which is more accurately defined to include the entire range of methods and tech-niques employed not only for the delineation of the sizes and shapes of markets but also for the evaluation of tactics and strategies useful for de-veloping and exploiting markets.

While market analysis and advanced methods of sales forecasting derive from the relatively young fields of statistics, survey methodology, and econo-metrics, the practice of prediction—commercial prediction no less than any other kind—has a very long history. Before the Delphic liturgy was defined, the auguries were divined from the livers of bulls and the entrails of doves; and the ambiguities of the oracle may not have been less than some of the forecasts that today trumpet tomorrow's fortunes.

The process and the outcome of sales forecasting command general interest among business man-agers, since sales volume constitutes the most im-portant source of income for all but a narrow class of (financial) enterprises; and it is basic for corpo-rate planning with respect to plant, personnel, and investment. Marketing plans and the allocation of promotional budgets are, of course, importantly influenced by expectations of the level and distri-bution of market opportunities.

The methods of market measurement. In meas-uring markets, one is concerned with both industry and enterprise concepts—total generic product sales in an area, loosely referred to as "market potential," and enterprise or brand sales, which are some proportion of industry sales. This is the "market share" of the firm or brand. The sales fore-casts of particular companies normally depend on estimates of market potential (itself sometimes an inference from a general economic forecast), which are then adjusted for the firm's expected market share.

Methodological discussions of market analysis usually focus on sales or market potential. In prac-tice, of course, it is not always obvious what the most appropriate definition of "market" or "product" is. One speaks of markets in various contexts: the "gasoline market," for example, of which the "high octane market" is a segment. The "petroleum mar-ket" and the "liquid fuels market" are broader con-cepts—but narrower than the "energy sources mar-ket." Similarly, one often hears of the "high price" and "low price" markets, the "New York," the "west coast," and the "export" market. In estimating mar-ket potentials it is important to choose the relevant definition, but this choice is often influenced by the data available. [See MARKETS AND INDUSTRIES.]

While successful forecasting depends on gaug-ing the effects of changes in the firm's marketing policy, on competitive behavior, and on the con-

sequences of future events that may transform the environment, business planning often starts from estimates of present (recent) sales. It is common practice to estimate potential market size by taking recent industry volume as the first approximation to the measure of expected market size. Even this is not always easy. Not only are there difficulties in establishing a relevant definition of "industry," but data on recent industry sales are not as readily available as one might expect. Census data of various sorts offer authoritative figures on production and sales volume of fairly broadly defined product classes in the United States, but these tabulations do not appear at frequent intervals. More frequent compilations of industry statistics are by-products of excise taxes (e.g., gasoline and tobacco in the United States) and/or import duties. Other sources of industry sales-volume data are sometimes found in the publications and the archives of trade associations and of advertising media. Many firms find it useful to subscribe to one or more of the commercial subscription services that collect panel data from households and/or dealers for certain kinds of products. These panels provide much more detailed information on product movement—by brand, price level, and type of outlet, for example—than is available by other means. Finally, of course, it is possible to undertake special surveys of product volume and use.

In the absence of industry sales figures, and in order to avoid the expense of direct data collection, corollary or proxy data may be used to estimate market potentials. Data on complementary goods, for example, can serve this purpose—the market potential of automobile batteries for replacement can be estimated from data on the distribution of cars, sales of electrical appliances will be related to and limited by the number and location of wired homes.

Whatever the data sources of the market potential estimates, they are often available only on a national basis. One of the tasks of market analysis is to make the conversion to local and regional estimates. The conversion is characteristically made by distributing national figures in proportion to such measures as population, income, number of employees, and value added by manufacture, which are available for smaller geographic units.

The technology of sales forecasting. It is customary in the literature of forecasting to distinguish between short-term and long-term forecasting, although there is only rough agreement on definitions. "Short term" clearly refers to the monthly or quarterly outlook and many practitioners would include the annual forecast. "Long term" can safely

be attached to 10-year forecasts, but many technicians would so classify any predictions whose horizon is greater than one year. Forecasts for three years and five years are sometimes categorized as "intermediate range." Much (most) of the technology of forecasting is common to predictions of the various planning horizons, although truly long-range forecasts (e.g., for 10 and 15 years) depend heavily on trend analysis of such fundamental variables as population, productivity, income distribution, political developments, and leisure—all of which change slowly and are assumed to be stable in forecasts for any period up to a few years.

While few analysts would enthusiastically endorse Alphonse de Lamartine's observation that "History teaches everything, even the future," the fact is that the experience of yesterday and today constitutes all we know about tomorrow. The technology of forecasting includes methods for identifying relevant historical data and for manipulating them in ways which may make the record more meaningful and illuminating. The art of forecasting largely consists in interpreting historical data and in specifying those future events that will condition tomorrow's performance.

There are numerous ways of categorizing sales forecasting methods. It is convenient here to distinguish among the following: "judgment forecasts," including sales-force estimates; market surveys; market tests; time series analysis, including curve fitting; and regression analysis. While these various techniques are sometimes presented as mutually exclusive and alternative analytical tools, in practice full reliance is seldom placed on any single method; two or more approaches often supplement each other. Certainly, the forecast ultimately accepted as the basis for company planning almost always will reflect the intuitive estimates of senior management.

Judgmental approaches. Hardly anyone will quarrel with the assertion that intuition and judgment dominate the practice of sales forecasting. Ease, cheapness, and flexibility all combine to support the use of predictions of sales volume which rest unabashedly on the judgment of one or more persons in the firm. Judgment forecasts, whether made by individuals or committees, are dominated by the experience, perception, and intuition of the forecasters. The process cannot be separated from the performer(s) and replication is impossible. However inelegant the method may appear, impressionistic evidence suggests that the more rigorous statistical forecasting methods continue to play a subsidiary role in business planning.

Judgment forecasts are sometimes based on

sales-force estimates of future sales. It is hoped that sales personnel (and their managers) are familiar with the needs and circumstances of customers and the relative strength of competitive offerings. In some companies sales representatives systematically interview customers concerning their spending plans. Rarely, however, are sales-force estimates the sole basis of a company's forecast. Substantial editing is generally contributed by corporate staff and senior management.

While it is often claimed that salesmen (and their supervisors) are unduly optimistic and therefore generate faulty forecasts, evidence is hard to come by. It is not obvious that such a bias should consistently attach to their estimates, since the estimators' interest will be a function both of the character of the compensation plan and the particular use to be made of the forecast.

Market surveys. Whereas sales-force estimates rely on a survey of the forecasts of sales personnel, a more recent development has been that of the survey of buyer intentions. The market survey rests on a sample of potential buyers whose attitudes and/or intentions to purchase are solicited in person or by mail or telephone.

The survey has enormous appeal as a forecasting aid. It seems plausible that buyers should know (and be able and willing to say) what and whether they plan to buy in the future—especially if the future is not too distant. But this view assumes that consumers can predict what the future will be like as well as what they will choose to do if the future is as they expect it to be. Evidence on the validity of these assumptions is uncertain.

The Survey of Consumer Finances was initiated in 1946 by the Board of Governors of the Federal Reserve System (Juster 1964). These surveys, covering intentions to purchase durable goods (e.g., houses, automobiles, and major household appliances), are among the best-known and most thoroughly analyzed materials in the literature of forecasting. They are in many respects models of methodological nicety and generally far surpass ordinary commercial standards—and costs—of market investigation. Despite the relatively long history of these surveys and the superior methods and skills of the investigators, one must still characterize the method as more promising than certain. What does seem clear is that the survey method is best adapted to products involving relatively large expenditures and a fairly high degree of planning for purchase. In the case of family expenditures, homes and automobiles most clearly meet these conditions. In the case of industrial markets, expenditures for capital goods (e.g., expensive machinery and new

plant construction) obviously qualify. Indeed, surveys of spending plans for industrial capital goods have tended to yield more accurate forecasts than those for consumer goods.

Market testing. Another method used to estimate market potential is the market test. Employed primarily for new products and invading brands, the market test is essentially an "experiment" which eschews direct questioning of respondents in favor of measuring their behavior. Market experiments are not feasible for all product categories, and they are expensive even when confined, as they usually are, to one or a few markets. The test is most commonly employed for packaged consumer goods items—the frequently purchased branded food, drug, and household supply products of relatively low price and high turnover. Market tests by and large amount to "tryouts" in one or a few markets—typically cities or metropolitan areas—which are selected as test locations because they are considered to be representative and relatively self-contained and have trade outlets and advertising media which are amenable to experimentation.

Virtually nothing is publicly available on the predictive value of the test market as a forecasting method. Test marketing is above all else a private affair. One infers that it provides useful, if not precise, information from the fact that successful and sophisticated enterprises continue to employ the method. At the same time, some conspicuous commercial failures suggest that test marketing is far from infallible as a basis for estimating market potential. In an article on the predictive power of test marketing, the author concluded:

Despite its shortcomings, test marketing has provided a certain degree of service to marketing management. It has, without question, considerably narrowed the range of new product sales prediction error over forecasts arrived at by judgment, even experienced judgment. From a management point of view, however, for a technique as expensive as test marketing, and one that exposes the company's future hand to competitors, it would seem that we have a right to expect a much greater measure of reliability and accuracy. (Gold 1964, p. 16)

Time series analysis. Among the most frequently employed statistical forecasting techniques is that of time series analysis, which probes the record of past sales behavior in search of patterns that may be extrapolated. Historical sales, economic, and social data constitute time series which can be analyzed by statistical techniques of various kinds. But when measured against the task, the statistical tools are rudimentary and, some statis-

ticians believe, of dubious value. One persistent approach seeks indicating or "leading" series which signal the direction and, hopefully, the extent of movement in the "following" or "lagging" series. While experience has dampened the hope that many companies can find consistently reliable lead-lag relationships, the search has not abated and empiricism rules.

Past sales patterns are sometimes mechanically projected by methods of curve fitting and trend analysis. The results are extremely sensitive to the particular formulas chosen and are perhaps most often used in combination with the forecasters' best guesses about the state of key variables in the future and often with a substantial dash of reasoning by analogy.

Forecasting for the month or the quarter ahead is frequently characterized by relatively mechanical projections of recent sales, usually "smoothed" by one statistical device or another. The availability of computers and developments such as exponentially weighted projections of past sales, the weights declining as one incorporates earlier and earlier data, promise better short-term forecasts and improved inventory control in situations of highly complex inventory assortments and relatively strong seasonal demand.

In all forecasting it is well to have some criterion of success and, particularly, a measure of the extent to which forecasts do little but exploit the tendency for sales figures to show inertia, each period tending to be close to the experience of the immediately preceding period. This interest in a criterion underlies the so-called "naive models." The simplest of such models is the "no-change" model, that is, the forecasted sales for the period ahead will equal the sales of the current period. A somewhat more complex formulation would be that the direction and rate of change, rather than the absolute value, will persist. (These are, of course, simple methods of extrapolation.) Naive models have been used mainly as standards for evaluating alternative forecasting methods. Nonetheless, the notion underlying naive models can be expressed in various autoregressive statistical methods that have some promise of improving judgmental forecasts, even for periods as long as a year.

Regression analysis. Regression analysis, in its many forms, attracts increasing interest and use. The underlying idea is to exploit the statistical relationship evidenced in the past between the variable to be forecast and the so-called independent variables (e.g., income, population, prices) that may be related to it. There are numerous regression

analyses "explaining" the sales of various products, in the sense of showing a statistical relationship between sales and the independent variables. The prediction problem is then shifted from the dependent variables (sales) to the independent variable(s). Occasionally, of course, a lagged relationship can be shown to exist. Predicting from a regression analysis assumes stability of the past statistical relationships. As in all other statistical forecasting techniques, intuition and judgment are required to allow for changes in basic conditions that are neither reflected in historical data nor embraced by the statistical model.

The advent of the computer has made it possible to undertake more sophisticated (complex) manipulations of data than ever before. Computer programs make feasible the exponential smoothing of time series, stepwise multiple regression, the solution of systems of multiple regression equations, and simulation. But while the contributions of the computer promise wider use of complex forecasting techniques and offer improved opportunities for experimenting and testing alternative methods, the millennium is not yet.

Status and prospect. Despite the enthusiasm for sales forecasting and the exhortations that it constitutes the basis if not, indeed, the essence of business planning, the record is neither clear nor impressive. Accurate forecasting is still a wish rather than a fact. Distressingly little published information is available on the degree to which actual sales conform to forecast sales. One survey in the United States reported that there was an average deviation of 8 per cent between forecasts and actuals in 1955, but the average performance masks a wide range of deviations within and between industry groups (American Management Association 1956, p. 148).

In an English study Carter and Williams suggest some of the difficulty of making accurate sales predictions in the case of new ventures. In 57 per cent of the cases examined where expected and actual yields were at variance, the explanation was associated with "unforeseen changes of demand, or changes in the price of competing product." They properly observed:

The importance of changes in demand can be seen. Many of these were changes in the demand for an intermediate product, deriving from a change in the nature of, or the demand for, some final products of other industries. Given the long period which must often elapse between the final decision to go ahead with a new plant and the sale of its first product, it is clearly unreasonable to expect many of these com-

plex changes in demand to be foreseen; market research is not an answer to everything. (1958, pp. 90-91)

Limited information on European experience indicates mixed results, although the record of the "Munich Business Test" on quarterly forecasts of turning points is encouraging (see Theil 1958, chapters 4, 5).

There is an extensive literature on market analysis and sales forecasting, but most of it is preoccupied with technique and much of it is hortatory. And as Lorie observed a few years ago:

Progress comes most rapidly in any pragmatic discipline when adequate testing devices are available for measuring the success of current theories and procedures. Only by such testing is it possible to discard what has not succeeded and to cling to what has succeeded, for the purposes of further elaboration and refinement. These facts are considered self-evident in the field of meteorology, where most of the practitioners make their living by forecasting. As a consequence, a very extensive literature devoted to problems of evaluation has developed during the last seventy-five years. (1957, p. 177)

Unfortunately, the evaluation of sales forecasts is not general in the literature, and it is not common in industrial practice. Much too little is known about the predictive value of alternative techniques. The most sanguine would agree that there is much to be learned and that the task of prediction is to be approached with humility. Performance offers ample opportunity for improvement. The recording of methods and specific quantified forecasts with subsequent comparison with experience is certainly to be encouraged, not only as a means of educating technicians, but also as an opportunity for evaluating them.

CONSUMER RESEARCH

Consumer research, or marketing research, is the systematic gathering, recording, and analyzing of data and problems related to the marketing of goods and services. The "first law" of marketing has been expressed as "Make what people want to buy; don't merely try to sell what you happen to make." This dictum reflects the existence of a society in which consumers can and do exercise considerable freedom of choice in purchasing.

Present interest in the consumer can be viewed against a historical background of concern with two other factors: production and sales. Concern with production grew in importance during the industrial revolution and reached a peak in the most advanced countries in the early part of the twentieth century with the introduction of assembly lines and mass production methods. Then, as manufacturing efficiency increased and unit costs decreased, the need to dispose of the fruits of mass production gradually shifted management's attention to sales. Later, with the increase in competition for the buyer's dollar within the market, sellers found that they had to take an interest in the consumer and, thus, turned to marketing research to find out what it is that people want to buy. By telling the seller what people want to buy, the researcher helps him plan more efficiently, avoid failures (thus lowering costs to consumers), and provide consumers with a much wider choice of products.

Definition. The first and most important step in any marketing research undertaking is to define the problem. A clear statement of the problem is sometimes more than half the answer. Sometimes, too, after the problem is clearly outlined, it be-

comes obvious that the answer is already known or may cost too much to obtain. However, the cost of *not* having the answer must also be considered. If it is high, research may pay off. But if the price of being without the answer is minimal, marketing research may be uneconomical.

Once the problem has been defined and agreement has been reached as to what kinds of measurement will yield acceptable answers, the researcher designs his experiment. There are two basic ways of obtaining information about consumers: one is to ask them directly about their awareness, attitudes, and *opinions*; the other is to observe their actual *behavior* (other than verbal behavior). Depending upon the problem and the need for a precise answer, the opinion test (sometimes called "consumer jury") may be entirely adequate. This approach is often used because it is quick, relatively inexpensive, and often provides useful guidance for marketing decisions. Its major drawback is that consumers do not always do what they say they will, for a variety of reasons.

Motivation research. In an attempt to obtain better answers about why consumers act as they do, marketing researchers sometimes engage in motivation research (MR). The basic assumptions of MR are that people often have unconscious motivations and that indirect questioning and various projective devices may be more effective than direct questions.

In a study by Haire, for example, women were asked to describe a hypothetical individual solely on the basis of reading a grocery list prepared by that individual. There were two such lists, differing only in one item. One list included a reference to "regular grind coffee," and the other list referred to "instant coffee." Reactions to the second list showed that a significant number of women believed that the use of instant coffee characterized its user as "lazy." Once the reason for the product's lack of acceptance had been identified, the next step was to conduct an educational campaign, pointing out to housewives that by reducing food-preparation time, they could be with their families more—a use of the saved time that the experimenter assumed was consistent with the housewives' values (Haire 1950).

Other examples of such techniques include:

(a) *Word association.* ("Tell me the first word that comes into your mind when I say 'margarine.'")

(b) *Incomplete sentences.* (The respondent is asked to complete a sentence such as "The main reason my family doesn't have soup more often is _____.")

(c) *Balloon cartoons.* (An example would be

a comic strip drawing of two men in conversation. The balloon above one of the men might read: "John, I've been thinking about buying a station wagon." The balloon above John's head is blank, and the respondent is asked to suggest John's response.)

(d) *Narrative projection.* (Character descriptions are followed by questions about the kinds of attitudes or purchasing behavior that might be expected from the individuals described.)

(e) *Involuntary attention tests.* (The respondent is asked to look at one of two stimuli, and the one he picks up and examines first is assumed to be more interesting.)

There is little doubt that for certain kinds of problems, and particularly for certain kinds of products and services about which people are sensitive (such as personal-care items or small loans), the techniques of motivation research are appropriate and even necessary. But to claim, as some proponents did during the 1950s, that these techniques are the only way to measure attitudes properly is to go to extremes. The violent arguments of that era between the quality-oriented, small-sample MR specialists and the more traditional, quantity-oriented, big-sample researchers (dubbed "mere nose counters" by the MR group) have largely ceased. It became clear that MR, although it contributed many lasting insights and methods that eventually influenced even the most traditional researchers, was not the ultimate key to a complete understanding of human behavior.

Sampling. In most marketing research projects, once the problem has been defined, the next step is to decide how the sample of respondents is to be selected and how large the sample should be. It is important that the sample be free from systematic bias that could influence the conclusions. For example, a pre-election political survey of voter preference in upper-income suburbs would very probably be biased in favor of one political party; hence the sample findings could be quite different from the outcome of the actual election [see SAMPLE SURVEYS].

In marketing research it is not always desirable to sample from the total population. For example, if we wish to study reactions to a brand of hair tonic, we would be wise to qualify respondents as tonic users before proceeding to interview them about their reactions. Going still further, we might want to talk only to heavy users. For a wide variety of frequently purchased products it has been shown that the 50 per cent of buyers who are heavy buyers account for 80 to 90 per cent of total sales volume (Twedt 1964).

Since about half the population uses hair tonic, a fourth of the total population (the top half of users) accounts for nearly 90 per cent of all hair tonic consumption. There is increasing evidence that this relationship is not limited to packaged goods; the same basic pattern of purchase concentration is shown in sales of gasoline to credit card customers, in tolls for residential long-distance telephone calls, and even in sales of fractional horsepower motors to industrial buyers.

Since consumption varies by individual and by household, it seems appropriate to let each respondent "vote with his pocketbook" by weighting his response according to the amount of the given product he consumes. Suppose, for example, that research has been conducted to determine whether a package for cake mix should have a red or a blue background for package illustration. From hypothetical data in Table 1, one sees that although the total sample gives a majority vote to the package with the red background, the correct marketing decision would be to choose the blue background, since it is clearly more appealing to the heavy users, who account for about 85 per cent of total cake mix purchased.

Table 1 — Package-background preferences of cake-mix users*

	PREFERENCE	
	Red background	Blue background
Light users	450	50
Heavy users	150	350
Total	600	400

* Based on a sample of 1,000 cake-mix users (500 heavy users and 500 light users).

Questionnaires. After the necessary decisions have been made as to the purpose of the survey and who the respondents will be, it is necessary to make up a questionnaire. Questionnaires are often designed with a few general, bland questions at the beginning in order to establish rapport between interviewer and respondent. It is essential to ask the questions in such a way that the answer to a given question does not bias succeeding questions. For this reason many researchers build questionnaires by writing each question on a separate card, moving the cards around until a smooth sequence is achieved, and then transferring the questions to a regular questionnaire format. In major surveys the questions are "pretested" on a small group of 25 to 50 respondents, whose answers are not included in the final tabulations but are analyzed to see if the questions are clear and unambiguous. Revisions are made, and the questionnaire is again

pretested. It is not unusual for a survey to go through as many as a dozen revisions before the questionnaire is finally approved (Payne 1951).

Precoding and tabulation. The next step is to precode the questionnaires by assigning to, and printing next to, each question the appropriate code for machine tabulation of responses. Questionnaires can now be designed for optical scanning by machine, with the answers converted directly to either punched cards or magnetic tape; the cards or tape can be programmed to produce a page of "print-out" that is used as photographic copy for the final research report. The enormous economies in human time and the accompanying error reduction through elimination of tedious copying and hand tabulation and computing make it obvious that these developments will continue. The great potential economies of the computer in marketing research are not its only value; a beneficial side effect is that in order to use the computer to its maximum efficiency, the entire research project, including the final tabulations, must be thought through in advance, and this usually results in uncovering mistakes in planning at a time when they can be more easily corrected.

Quality control in field interviewing. Questionnaire surveys are usually made by interviewing organizations that specialize in this type of work. A list of such firms, and of others that offer a broader variety of services, including consulting, experimental design, and preparation of the final report with recommendations for action, is contained in *Bradford's Directory of Marketing Research Agencies*, which lists 350 firms in the United States and abroad (Bradford 1965-1966).

After the interviewing organization has been selected, it is customary to hold a briefing session with the project leader, the interviewing supervisors, and the interviewers in order to give detailed instructions on how the interview is to be conducted. Any questions the interviewers have should be answered at this time. Often they will be told not to proceed after the first day of interviewing until the field supervisor has had an opportunity to review the quality of work done during that day.

As the field work is progressing, or immediately after it is completed, 10 to 20 per cent of the interviews are validated in one of several ways: reinterview, a telephone call, or by mail. During these follow-up procedures, the supervisor verifies that the interview actually took place, and a few key questions may be repeated to check for report consistency. When the work of a given interviewer seems irregular, all the interviews turned in by

that person are rechecked. If, as occasionally happens, it develops that the interview was not made and that the questionnaire has been faked, the interviewer is not employed again by the same organization. One of the weakest links in the entire data-gathering and data-processing chain is the failure to validate questionnaires properly [see QUALITY CONTROL, STATISTICAL].

Recommendations for action. If the objectives of a research survey have been clearly defined, the right questions asked of the right people in order to answer these objectives, and the field work properly supervised, the two remaining tasks—tabulation and analysis, and report preparation—should be fairly routine. There are, however, two major conflicting viewpoints about the extent to which the researcher should make firm recommendations for marketing action.

One group of marketing executives tends to regard the researcher primarily as a technician from whom only "the facts" are wanted, with no interpretation or conclusions about appropriate courses of action. The other viewpoint is reflected by Theodore Levitt of Harvard University, who says,

Expertness [in marketing research] encompasses much more than the elaboration and use of formal techniques in research and analysis. More than anything else it should be viewed as involving imaginative audacity in the interpretation of data and events and in formulating positive action-oriented proposals for management's consideration. . . . Too often nothing is permissible in the way of making policy or entertaining ideas unless the data are so unambiguously in favor of proposed policies or ideas that even the elevator operator can see their merit. (1962, pp. 187-190)

Observing behavior. Most of the discussion up to this point relates to the gathering of opinions through survey research. There are many other ways in which marketing research can be conducted. Observing and recording consumer behavior takes many forms. Legibility tests of an advertisement, for example, can be made by determining the amount of illumination or length of exposure required to allow reading of the sales message. It is even possible to measure behavior which the respondent is not consciously aware of, such as pupillary dilation while viewing a product or an advertising stimulus. Or suppose that we wish to determine the proportion of consumers that will read the statement of ingredients on the package label of a new food product. It is a simple matter to observe shoppers at the moment of buying and record the number of seconds they examine each package before selecting it.

Another major method of behavioral research in marketing is to conduct controlled advertising and sales tests in selected areas. Two cities may be matched, for example, on the basis of their previous sales of a given product. An advertising campaign may then be undertaken in one city, and a different campaign (or perhaps no advertising) employed in the other city. After a predetermined time period sales results are compared for the two cities. Variations of this method may include much more complex statistical procedures and may involve factorial and Latin-square experimental designs, with many cities or retail outlets included in the test. The measures may be actual sales, the proportion of consumers who are aware of a given brand name, or the proportion who can recall specific sales points about the product. [See EXPERIMENTAL DESIGN.]

Subjects for marketing research. The most common research activities of 1,660 companies are shown in Table 2.

Table 2 — Market research activities*

Activity	Companies involved (per cent)
Sales and market research:	
Development of market potentials	68
Market share analysis	67
Determination of market characteristics	67
Sales analyses	66
Establishment of sales quotas	57
Distribution and costs studies	52
Test markets, store audits	37
Consumer panel operations	27
Sales compensation studies	44
Studies of premiums, coupons, sampling, deals	29
Product research:	
New product acceptance	63
Competitive product studies	65
Product testing	57
Packaging research	45
Business economics and corporate research:	
Short-range forecasting (to 1 year)	62
Long-range forecasting (over 1 year)	59
Studies of business trends	58
Profit and/or value analysis	53
Plant and warehouse locational studies	44
Diversification studies	49
Purchase of companies, sales of divisions	44
Export and international studies	39
Linear programming	35
Operations research	29
Program evaluation review technique studies	18
Employee morale studies	32
Advertising research:	
Motivation research	30
Copy research	37
Media research	47
Evaluation of advertising effectiveness	48

* Based on activities of 1,660 companies.

Advertising research. Advertising research is a special application of marketing research but employs many of the same techniques and methods. The task of advertising research usually is to find answers to one or more of the following questions: (1) What shall we say? (2) How shall we say it? (3) Where, when, and how often shall we say it? (4) How well did we communicate the intended message? These questions are investigated, respectively, in motivation research, copy research, media research, and evaluation research [see ADVERTISING, article on ADVERTISING RESEARCH].

Growth of marketing research departments. Of 1,660 companies surveyed more than half reported having a marketing research department (American Marketing Association 1963). Research departments are most common among companies that manufacture consumer goods (62 per cent have them), industrial companies (60 per cent), and publishers and broadcasters (57 per cent). The bigger the company, the more likely it is to have a research department. The research department is a fairly recent addition to corporate staffs; more than half of the departments in the survey had been formed since 1955. Even the companies that do not have formal marketing research departments carry on such research, either through their own personnel or through outside consulting firms. Between 1960 and 1965 marketing research budgets as a percentage of sales increased for both consumer and industrial companies.

It is clear that marketing research has matured greatly since 1955 and that it has gained increased acceptance from business management. It is also true that marketing research has not yet reached its full potential.

MARKETS AND INDUSTRIES

The market is the stage on which economic actors—firms, households, and unions—meet and make key economic decisions for society. Out of the process of market exchange come the prices, wages, and profits that serve to determine the allocation of the economy's resources and the distribution of the national income.

The market is thus a central concept in economics. It is, however, an elusive concept. It may mean merely the geographical place where exchange takes place—a nodal point where buyers and sellers meet to exchange goods and services. But the concept of the market as economists use it also embraces the whole set of circumstances that surround the process of exchange, and indeed it concerns as well the outcomes of the process of exchange. Thus we speak of market structure and market behavior and market price. Firms and households may take conditions in the market as external to them, and such conditions affect their behavior. But this behavior in turn affects market results and, indeed, may determine what is the market.

The market in the most general sense is the entire web of interrelationships between buyers, sellers, and products that is involved in exchange. The appropriate definition of the market depends upon which aspects of this web are of interest at the time; for different problems there are different appropriate definitions.

Historically and in much of common usage "the market" means a place where buyers and sellers meet to buy and sell goods. But while this usage serves well enough to identify the Fulton Fish Market, it provides little insight into what is meant by the used-car market, the stock market, the labor market, the mortgage market, or the black market

in Japanese yen. Within the market, however defined, buyers and sellers negotiate the exchange of goods or services. A market definition may focus upon what the products are, as the market for cement, aluminum cable, or wheat. In this usage it is common to speak of the market as an industry. Alternatively, however, it may focus upon who the buyers are, as, for example, the market for loans to Chicago borrowers. It may focus upon who the sellers are, as the market for engineers or the market in which the integrated oil companies operate. Market definition may focus upon the rules by which the market is run, as in an auction market, or upon when goods are to be exchanged, as in the distinction between a present and a futures market. Finally, geographical definition may concern where buyers or sellers reside or do business as well as where they meet to exchange. In this sense the New York Stock Exchange is often regarded as an international securities market.

None of these bases for definition is without interest some of the time. In general, differences in focus will lead to differences in designation of which transactions belong in a market. The market is a concept with many dimensions.

The market in economic theory

Economists use the word "market" in two substantially different senses. While they have etymological precedent for this—the Latin root *mercatus* means either the place of or the method of contact between buyers and sellers—the result is often confusion.

The first sense in which economists use the word concerns the general conditions under which buyers and sellers exchange goods and services. The conditions may be summarized in a series of alternative theoretical market structures, such as "perfect competition," "monopoly," "oligopoly," and "monopolistic competition." [See COMPETITION; MONOPOLY; OLIGOPOLY.] These theoretical structures, or models, make assumptions about such things as the number of sellers and buyers and their perceptions of each other and yield predictions about market behavior. In turn this predicted behavior leads to predictions about market results: what will be the prices, quantities, and qualities of outputs that emerge from the market. Market structure is not one-dimensional, but it is often convenient to think of different market structures as differing from one another in terms of the kind and degree of competition that they lead to.

The second sense in which the word is used is to delineate the boundaries (usually geographic) that identify specific groups of buyers, sellers, and

commodities. This concept of the market is designated *extent of the market*. In this sense we define the fluid-milk market for the New York City area or the upper Midwest cement market by an appropriate map.

Up to a point these two usages are both separate and separable. One does not need geographic boundaries to derive predictions about how, for example, a perfectly competitive market works in equating demand and supply, nor does one need theoretical models of market structure to describe or delimit the Fulton Fish Market. The need to confront these separate aspects of a market arises whenever economists wish to use economic theories of market structure to make predictions about the behavior or performance of real-world markets; it arises as well if they wish to use observed data about real-world markets to test the predictions of their theories; it arises, further, if one wishes to use economic conclusions about market behavior and performance in establishing or enforcing public policies that relate to the behavior of actual industries or firms. Since these are among the important uses of economics, it arises often.

The number of participants in the market is held to be a key factor in market structure, and thus in market behavior and in market results. The number of participants in a market will, however, vary as we change the boundaries of the market. Market structure and market extent are thus interrelated in applications. The great hazard in analyses of economic markets is the circular, or prediction-determining, definition.

Defining market extent by its structure. Most well-defined theories of market structure contain implicit rules for delineating which transactions belong in the market. Using such implicit rules is superficially an appealing way to solve a difficult problem. Except in rare cases it proves quite unsatisfactory. Consider market definitions under perfect competition and under monopoly.

Under perfect competition. A central prediction of the theory of perfect competition is that the price of all transactions will tend to uniformity, allowing for differences in transportation costs. Empirically, the boundaries of a *perfectly competitive market* may be established by searching for the area over which transactions occur at common prices. This definition of a market has an honored past and a wide range of contemporary acceptance. It is the definition used by Cournot (1838, chapter 4), popularized by Alfred Marshall (1890, p. 327 in 1920 edition), and repeated in leading contemporary texts (Stigler 1942, p. 92 in 1947 edition).

One drawback of this definition is that actual price behavior in such a market cannot be used to test the prediction of uniformity of prices. A more serious difficulty concerns the interpretation of transactions that occur at other than the adjusted common price. Do they represent transactions in a different market or do they provide evidence that this market is in fact not a perfectly competitive one? The implications of these two possibilities are totally different. In U.S. law, for example, the merger of two firms is legal if they are in quite separate markets but may be illegal if they are in the same, imperfectly competitive market. Using uniform price behavior to define market extent would be satisfactory if such behavior were a common implication of all theories of market structure; this, however, is not the case.

Under monopoly. The theoretical model of monopoly comprehends a situation in which there is but a single seller of the commodity (or a group of sellers who act as if they were under a single coordinated management). The implicit market for a monopolized product consists of all transactions in the commodity in which the monopolist is the seller. It is *not* a prediction of the theory that the price need be uniform among all customers, since the monopolist can discriminate among buyers. It is a prediction of the theory of discriminating monopoly that prices will be uniform only among subgroups of customers who can resell the commodity or among whom demand elasticities are approximately equal. Were we to apply the implicit competitive definition of a market in a situation that is, in fact, that of a discriminating monopolist, the group of transactions which occur at a common price would represent only a small part of the total relevant market.

The major deficiency of defining a market on the basis of theories of market structure is that different market structures contain different implicit rules for definition of the market. Indeed, their reason for being is that they make different predictions about market results. To define the market according to the price behavior exhibited destroys any possibility of using the market so defined to say anything about price behavior, and it prejudices the question of which market structure is the relevant one for making predictions. An empirically useful market definition must be independent of the alternative theoretical models of market structure, if we wish to test or to apply those theories.

Defining market extent by demand and supply alternatives. Any particular buyer or seller has a definable set of alternative sources of supply or

demand which he considers available to him. From his point of view the relevant market is the set of these alternatives. This kind of individualized definition of a market would be of little general use if there were not important clusters of buyers and sellers for whom the relevant market was approximately the same; suppose there are such groups and that it is thus feasible to define markets that apply to significant numbers of transactions.

As a logical matter, market extent defined in this way may also be circular. The perceptions of, for example, a buyer as to which are the real alternative sources of supply depend upon the prices that prevail. A housewife who says she will never go across town to shop for food means it only within limits. A big enough "sale" will change her view. Thus if prices are, in fact, uniform as among sellers, the radius of the market extent around a customer will be much smaller than the market to which he might turn if prices were not uniform. Some Californians buy cars in Detroit if prices on the west coast get too far out of line.

Empirical approximations to definition

While as a logical matter there is no satisfactory definition of a market that identifies the relevant transactions independent of the market results, reasonable markets do exist in many commodities. While everything in principle depends upon everything else, in many cases the interactions and feedbacks are small enough to be negligible. Bicycles and sports cars are not in the same market, although there conceivably exists a set of prices that would lead to large-scale substitution of one for the other. As a practical matter cement is so rarely sold outside of a radius of 200 miles from the factory that a regional cement market may be defined.

The basic empirical problem of market definition is to define the range of alternatives to which a buyer or seller may *practicably* turn and to identify the sets of transactions whose outcomes are sufficiently interrelated that to subdivide them further invites error. One definition of an industry is as "a gap in the chain of substitutes"; a parallel definition of a market is as "a gap in the chain of alternatives." As a logical matter it has been argued that industries do not exist (Triffin 1940) and that all firms must be viewed either alone or as part of a generally interdependent network. Most economists reject this nihilistic view and believe the industry is a useful aggregate concept. Similarly, the market is a useful aggregation of sets of related transactions.

Suppose we seek an empirical approximation of the set of real, practicable alternatives. We must

ask: "Real alternatives to whom?" One may focus upon the products or the sellers that are real alternatives to a particular group of buyers, one may instead ask what are the alternative sources of demand to a group of sellers, or one may ask what are the products that are effective substitutes for a particular product. There are, indeed, many aspects of each of these different ways of looking at the set of alternatives. Consider the producer of a given product: he may at one time be concerned with the group of other sellers of this product; at another time he may be concerned with other products that are technologically similar so that they represent real alternatives to him in production; at still another time he may be concerned with different products that his customers may regard as substitutes for his product. Of the hundreds of possible ways of defining sets of alternatives, two are of major interest to students of economic markets and how they work.

The first is the *real alternative sources of supply available to a defined group of buyers*. We may ask, for example, what are the sources of supply of credit available to the small businessman; we may be concerned with the sources of supply of safety glass to automobile manufacturers; or we may be concerned with the sources of supply of automobiles in the \$1,500–\$2,500 price range to buyers living in Peoria. Much of the public concern with competition is concerned with preserving a sufficient number of independent sources of supply so that every group of customers has genuine alternative sources of supply. The legislative concern evidenced in the major antitrust laws is centrally concerned with preserving effective competition in markets defined in this way.

The second is the *group of relevant rivals to a particular seller*. This concept of the market is crucial to understanding the market behavior of sellers. The number of rivals that a seller has and the nature of the interactions between them are hypothesized to be major determinants of the price and product patterns that emerge in an industry. Indeed, the very concept of an industry rests upon the identification of a group of sellers in substantial rivalry (actual or potential) with one another. Economists largely concerned with industrial structure and behavior regard this focus as central to the definition of the market.

Implicit in each of these definitions is the notion that a distinct "product" or group of products exists. The classification of products into meaningful "industries" is a major concern of the U.S. Bureau of the Census and other statistical agencies. The recognition that for different purposes

different clusters of products are relevant has led to the development in the United States of a Standard Industrial Classification (SIC) at several levels of aggregation. There are seventy-eight "2-digit" industries, hundreds of "3-digit" industries, and several thousand "4-digit" industries. By appropriate recombinations of the 4-digit industries a very much larger number of industries may be defined. The focus of the SIC is on the supply side rather than the demand side, and SIC industries are more nearly appropriate to the identification of interrelated sellers than of alternatives to buyers.

Markets defined in these ways overlap but do not coincide. Every transaction involves a buyer, a seller, and a well-defined product. It may, however, be a transaction in several different markets. Consider, for example, the purchase of a new compact Chevrolet by an individual living in St. Louis. From the buyer's point of view the relevant alternative products may have been any of four or five models of new cars or any of a number of used cars in the same price range. (The list of alternatives will certainly not include a truck or a tractor and almost certainly will not include a new Cadillac.) The relevant sellers will be the new- and used-automobile dealers in a definable geographic region centered largely on St. Louis, as well as private sellers with whom the buyer may make contact.

To the General Motors Company the transaction appears in a very different light. Its rivalry with Ford and Chrysler and American Motors for the new-car dollar is nation-wide and includes Buicks and Cadillacs as well as Chevrolets. At the same time, the compact-car market—in which the various American manufacturers are in open competition with certain foreign manufacturers, particularly Volkswagen—involves a different set of rivalries.

From the product point of view, the transaction occurred in SIC industry 37, Transportation Equipment; in industry 371, Motor Vehicles and Motor Vehicle Equipment; and in industry 3717, Motor Vehicles and Parts. Even the smallest of these is a substantially comprehensive classification including the manufacturing or assembling of (among other things) passenger automobiles, trucks, ambulances, and fire engines and also including the parts that make up such motor vehicles, such as axles, radiators, drive shafts, exhaust systems, universal joints, and automobile bumpers. For many purposes SIC 3717 is much too broad; an automobile muffler and an automobile bumper are not in any sense substitute products. The statistical problem of industry definition is made complex by

the fact that some firms make a large variety of such component products and others specialize. For other purposes the definition of industries in the SIC is too narrow. Multiproduct firms may operate in many industries, and their wage policies and their labor market negotiations may extend across industry lines. All production workers of American Motors, whether they are making cars or refrigerators, are covered by contract negotiations with the United Automobile Workers.

The market to buyers. Major impetus to empirical definition of markets in the United States has been a by-product of the Anti-merger Act of 1950 (the so-called Celler-Kefauver Act). It made very general a prohibition on mergers "where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition, or to tend to create a monopoly."

A first step in every one of the cases involving this statute is the definition of the relevant market. Pathbreaking opinions in a series of antitrust decisions have sharpened the notion of what is a relevant market, as well as defining the legal issues involved. It is clear that one can always define a sufficiently localized geographical area in such a way that there is but one seller of a particular product; conversely, one can usually define an area so broadly as to make the effect on competition appear trivial. Every merger leads to the disappearance of one seller. But one out of how many? For example, the 1961 merger of the Continental Illinois National Bank and the City National Bank reduced the number of banks in the 200 S. block of LaSalle Street, Chicago, from 2 to 1, the number of business district banks from 16 to 15, and the number of banks in the Chicago Metropolitan Area from 219 to 218. For the whole United States there were about 14,000 commercial banks. After the merger there was one less.

Recent court opinions have established guidelines:

... the boundaries of the relevant market must be drawn with sufficient breadth to include competing products ... to recognize competition where, in fact, competition exists. (*Brown Shoe Co. v. U.S.*, 370 U.S. 294, 326, 1962)

The relevant market is the area to which customers can practicably turn for supplies. (Paraphrase of *U.S. v. Philadelphia National Bank*, 374 U.S. 321, 1963)

The proper question, ... is not where is the customer located, but what is the geographic area of effective competition for his patronage. (*U.S. v. Manufacturers Hanover Trust Co.*, CCH Trade Cases 71,708, pp. 80,744, 1965)

A relevant geographic market cannot be defined, however, solely on the basis of where ... banks have actually done business, or even where customers have actually turned for their banking needs. The market must be drawn also on the basis of potential competition. ... Where could customers practically turn for alternative sources of supply? (*ibid.*, pp. 80,746)

These are sensible guidelines; implementing them is hard. The problem is in relating observation to guideline. A customer buys from a particular seller for any or all of a number of reasons: it may be habitual, it may be convenient, it may be a matter of some indifference, or, importantly, it may be necessary. Defining the relevant choices of the buyer is in fact defining the group of sellers from one of whom it is necessary that he buy. Put differently, if we can define sellers from whom it is impracticable to buy, we have defined sellers outside of the relevant market. If one is to base empirical delineation of the extent of a market upon observations of which sellers are in fact utilized by buyers, the key problem is to differentiate the factor of necessity from that of convenience.

A housewife in a moderate-sized city will in general have a dozen or more supermarkets at which she may conveniently shop, and another dozen at which she might shop if there were any real reason to do so. In fact she will usually tend to shop at two or three, because, other things being equal, she has certain preferences. Indeed she may only shop at one. But this one is an explicit or an implicit choice from the larger set of practicable choices. It is the larger group that constitutes her real opportunities and that defines the market.

The determinants of a customer's choice of a supplier may in general be several. Some of these are (1) portability of the product, (2) cost of transportation of the product, (3) information about the availability and conditions of supply of the product, (4) acceptability of the customer to the seller, (5) price of the product, (6) convenience, and (7) chance and habit. These factors may be related to one another: for example, while there are limits to the geographic range over which fresh milk and live lobsters can be transported without spoiling, these limits may be extended by increasing costs of delivery. Refrigerated trucks and railroad cars extend the markets for fresh produce, some Maine lobsters are shipped to the Midwest by air (but none are shipped to San Francisco), and so on. Similarly, information can be gathered, but at some cost and some inconvenience. What is of concern in defining markets is the distinction between the first four listed factors (singly or in interaction), which represent real limits on prac-

licable alternatives, and the last three, which represent instead the bases of choices among real alternative sources of supply.

As a practical matter geographic market definition becomes relatively easy when one of the first four considerations exercises a dominant limitation on sources of supply. Consider a few examples. For commodities such as cement, for which transportation cost per unit is a high fraction of unit value, the geographic limits on choice of suppliers is very clear. It is easy to define the relevant cement market for a given customer. The relevant housing market for an individual is delimited by distance from his work, by his income, and in some cases, additionally, by his race. The market for a business loan for a small business is effectively limited to those financial institutions that will accept local credit evaluations. Such a small borrower is typically limited to his home city or a portion thereof. Purchase of a used car tends to be limited more by available information than by anything else. On the other hand, well-organized markets in securities make the supplier from whom one buys 100 shares of General Motors stock a matter of substantial indifference. The borrowing of \$1 million for working capital by a national corporation is not practicably limited to any small geographic region.

Observing from whom each of the individual members of a large group purchases will tend to define the relevant geographic market if transportation cost, portability of product, information, or acceptability provides a binding constraint on available alternatives. Chance, convenience, and habit will average out over a large group, and over time variations in price will average out as well. The fact that over 90 per cent of all loans to businesses with assets of less than \$50,000 are made by banks in the same city, county, or metropolitan area strongly suggests that the relevant geographic market is limited. Of customers with assets of over \$100 million, only one-third borrow from local banks. (As this example suggests, one can perhaps infer geographic limitation by observed behavior. This is a complex matter of statistical estimation, discussion of which is inappropriate to this article.) Where no binding limitations of these kinds can be identified, geographical delineation of market extent is virtually impossible.

The market to the seller. Identifying the relevant rivals to a particular seller is typically a very much easier matter than identifying markets for customer groups, particularly for manufacturers of major commodities. But not always. Some forty firms in the United States manufacture electrical equipment, but only six of them manufacture tur-

bine generators, only four manufacture meters, about a dozen manufacture industrial control equipment. And General Electric and Westinghouse are clearly in rivalry with General Motors in the manufacture and sale of refrigerators, though they are no part of the automotive industry.

In practice the relevant group of rivals has to be defined in the context of a particular problem. With respect to price determination, of primary concern in many cases, sellers who regard each other's commodities as close substitutes and employ consciously parallel price policies clearly are in the same market. Products whose prices move closely together over a sufficient period of time to permit other influences to vary are usually regarded as in the same market, and the suppliers of them are considered to form an industry. Again, difficulties in precise definition exist but need not prevent reasonable estimation of related groups of suppliers who sell in the same market.

The many markets for a commodity. Consider the market(s) for business loans. A Federal Reserve Board survey in 1955 revealed over 1.2 million outstanding loans by some 7,000 U.S. member banks, amounting in aggregate to over \$30,000 million. Most of these loans were very small: over 1 million were for less than \$25,000, and they accounted for only one-sixth of the dollar total. On the other hand, 42,000 of these loans were for over \$100,000, and they accounted for two-thirds of the total dollars of outstanding loans. There is no doubt that there is a national market for very large loans. There is also little doubt that small loans are largely limited to local markets. There are thus hundreds of local markets and a national market as well. (There may be regional markets in addition.) Let us consider the definition of one such local market, that for the Chicago Metropolitan Area (CMA).

In a total of 20,500 loans representing about

Table 1 — Loans involving CMA bank or borrower (millions of dollars)*

Location of bank \ Location of borrower			
	In CMA	Not in CMA	All
In CMA	1,125 (16.5)	1,224 (2.5)	2,349 (19.0)
Not in CMA	756 (1.5)		
All	1,881 (18.0)		

* Number of loans in thousands in parentheses.

Source: Special unpublished tabulation from Federal Reserve Board 1955 loan survey.

Table 2 — Loans under \$100,000 involving CMA bank or borrower (millions of dollars)*

Location of bank	Location of borrower		All
	In CMA	Not in CMA	
In CMA	215 (14.8)	36 (2.3)	251 (17.1)
Not in CMA	20 (0.8)		
All	235 (15.6)		

* Number of loans in thousands in parentheses.

Source: Special unpublished tabulation from Federal Reserve Board 1955 loan survey.

\$3,105 million in value, either borrower or bank was located in the CMA. What fraction of this business was in the CMA "local loan" market? Table 1 shows this total business classified by location of bank and borrower. For only \$1,125 million were both bank and borrower in the CMA. Chicago-located borrowers borrowed \$756 million from other banks, and Chicago banks loaned \$1,224 million to other borrowers. Some of the loans for which both bank and borrower were located in the CMA were very large loans, in which dealing with a local bank was a matter of convenience rather than necessity. Table 2 presents all loans with an outstanding balance of less than \$100,000. Of these about 15,000 loans, representing \$215 million, were between CMA banks and CMA borrowers. Judge MacMahon (in the *Manufacturers Hanover* case) suggested that only business loans under \$100,000 should be considered limited to the local market. If he is correct, then the transactions in the CMA local market of \$215 million are but a small fraction of the total transactions involving Chicago banks or Chicago customers.

Definition of a local market for loans no doubt requires more sophisticated measures than merely the address and size of loan used here. One would wish to pay attention to the size of the borrower, the nature of his business, his other sources of funds, and so on. Further, one would wish to consider nonbank suppliers of funds as well. But the illustration is suggestive.

Does it really matter how one defines a market? In some cases it matters very much. For example, in the CMA bank illustration the share of the market of the four largest suppliers (called the 4-firm concentration ratio) varies enormously as the definition of the market is changed. For 1955, the four largest Chicago banks made 84 per cent of the dollar volume of business loans of banks in the

CMA, 42 per cent of the dollar volume of loans to CMA located borrowers, but only 25 per cent of the dollar volume of loans of under \$100,000 to CMA borrowers. These are major differences in terms of the relevant theoretical model to apply: 84 per cent is in the range where monopolistic models are often invoked; 25 per cent is near the competitive level. These differences are also important in terms of the legal status under antitrust laws. To take a different example, failure to recognize the geographical limits to the economical shipment of cement would lead to the conclusion that the U.S. cement industry has dozens of small sellers. In fact regional cement markets are highly concentrated and in some cases have but a single supplier.

The concept of a market is multidimensional and it is complex, but reasonably accurate delineation of markets is required if economic theory is to be brought into contact with economic observation. No single definition serves the many uses to which the concept is put; the relevant definition must be suited to the particular application required. Logical difficulties exist in attempting to define market extent independent of market behavior and market performance. Notwithstanding these difficulties, there is scope for approximations to the extent of relevant markets. These require both care in formulation and sophistication in empirical estimation. No greater barrier exists to the fruitful application of economic theory than the failure to forge the links to observable data. The operational definition of economic markets is such a link.

MARKOV CHAINS

A Markov chain is a chance process having the special property that one can predict its future just as accurately from a knowledge of the present state of affairs as from a knowledge of the present together with the entire past history.

The theory of social mobility illustrates the idea. Considering only eldest sons, note the status of successive generations of a particular male line in a society divided into three classes: upper, middle, and lower. If we assume the movement of a family among the three social classes is a chance process—governed by probabilistic laws rather than deterministic ones—several possibilities present themselves. An independent process represents a perfectly mobile society: the probability that a man is in a particular class depends in no way on the class of his father. At the other extreme is a society in which the probability that a man is in a particular class depends on the class of his father, that of his grandfather, that of his great-grandfather, etc.

A Markov chain is a process of intermediate complexity: the probability that a man is in a given class may depend on the class of his father, but it does not further depend on the classes of his earlier antecedents. For instance, while upper-class and middle-class fathers may have different probabilities of producing sons of a given class, an upper-class father whose own father was also upper class must have the same probability of producing a son of a given class as does an upper-class father whose father was, say, lower class. (This example will be used to illustrate each concept introduced below.)

No chance process encountered in applications is truly independent—in particular, no society is perfectly mobile. While in the same way no natural process exactly satisfies the Markov chain condition, many of them come close enough to make a Markov chain model useful.

Formal definitions. For an exact formulation of the Markov chain concept, introduced in 1907 by the Russian mathematician A. A. Markov, imagine a system (family, society, person, organism) that passes with each unit of time (minute, hour, generation) from one to another of the s states E_1, E_2, \dots, E_s . (Upper class, E_1 , middle class, E_2 , and lower class, E_3 , are the states in the social mobility example.) Assume that a chance process governs the evolution of the system; the chance process is the collection of probability laws describing the way in which the system changes with time. The system is that which undergoes change; a particular analysis may involve many systems of the same kind (many families, or many societies, etc.), all obeying the same process or set of probability laws.

Since the system passes through various states in sequence, time moves in jumps, rather than continuously; hence the integers 1, 2, 3, \dots provide a natural time index. Denote by $P(E_k|E_i, E_j)$ the conditional probability that at time $n+2$ the sys-

tem is in state E_k , given that at times n and $n+1$ it was in states E_i and E_j in that order; and similarly for longer or shorter conditioning sequences of states. We make the usual assumption that the conditional probabilities just defined do not depend on n (that is, the conditional probabilities do not change as time passes). The process is a Markov chain if $P(E_k|E_i, E_j) = P(E_k|E_j)$, $P(E_i|E_i, E_j, E_k) = P(E_i|E_k)$, $P(E_m|E_i, E_j, E_k, E_l) = P(E_m|E_l)$, etc.

The transition probabilities $p_{ij} = P(E_j|E_i)$ determine the fundamental properties of the Markov chain; they form an s by s transition matrix $\mathbf{P} = (p_{ij})$, the basic datum of the process. (A matrix such as \mathbf{P} that has only nonnegative entries and has rows summing to 1 is called a stochastic matrix.)

An independent process can be considered a special sort of Markov chain for which $p_{ij} = p_j$ (that is, the p_{ij} do not depend on i): the rows of \mathbf{P} are all the same in this case. The second-order transition probabilities provide a second example of information contained in \mathbf{P} . If the system is presently in state E_i , then the conditional probability that it will pass to E_j and then to E_k in the next two steps is $P(E_j, E_i)P(E_k|E_i, E_j) = p_{ij}p_{jk}$; hence the conditional probability that the system will occupy E_k two time units later is

$$p_{ik}^{(2)} = \sum_{j=1}^s p_{ij} p_{jk}.$$

(Summing over the index j accounts for all the possible intermediate states.) But this second-order transition probability $p_{ik}^{(2)}$ is just the (i, k) th entry in \mathbf{P}^2 (the matrix \mathbf{P} times itself in the sense of matrix multiplication).

Table 1

	E_1	E_2	E_3
E_1 (upper class)	.448	.484	.068
E_2 (middle class)	.054	.699	.247
E_3 (lower class)	.011	.503	.486

Social mobility in England and Wales is approximately described by a Markov chain with transition matrix shown in Table 1. (These numbers must, of course, be arrived at empirically. The problem of estimation of transition probabilities is discussed later.) For example, a middle-class man has chance .054 of producing a son (recall that only eldest sons are considered here) who enters the upper class. Now the chance that a man in the upper class has a middle-class grandson is $p_{21}^{(2)} = (.448 \times .484) + (.484 \times .699) + (.068 \times .503) = .589$, while the chance that a man in the middle class has a middle-class grandson is $p_{22}^{(2)} = .639$.

Notice that these last two probabilities are different, which raises a point often misunderstood. The Markov chain definition prescribes that an upper-class man with upper-class antecedents must have the same chance of producing a middle-class son as an upper-class man with lower-class antecedents has. But influence—stochastic influence, so to speak—of a man on his grandson, which does exist if $p_{12}^{(2)} \neq p_{22}^{(2)}$, is entirely consistent with the definition, which requires only that the grandfather exert this influence exclusively through the intermediate generation (the father).

To describe natural phenomena by Markov chains requires idealization; the social mobility example carried through here makes this obvious. Since Markov chains allow for dependence, however, they can with satisfactory accuracy account for the evolution of diverse social, psychological, biological, and physical systems for which an independent chance process would make too crude a model. On the other hand, Markov chains have simple enough structure to be mathematically tractable.

As another example of an approximate Markov chain, consider sociological panel studies. A potential voter is asked his party preference each month for six months preceding an election; his answer places him in state E_1 (Republican), E_2 (Democrat), or E_3 (undecided). The voter's progress among these states (approximately) obeys the Markov rule if, in predicting his August preference on the basis of his previous ones, one can without (essential) loss disregard them all except the most recent one, namely that for July (and similarly for the other predictions). In learning theory, Markov models have proved fruitful for describing organisms that change state from trial to trial in response to reinforcement in a learning process. (See Bibliography for applications in such areas as industrial inspection, industrial mobility, sickness and accident statistics, and economics.)

Mathematical analysis. The transition matrix \mathbf{P} determines many of the characteristics of a Markov chain. We have seen that the (i, j) th entry $p_{ij}^{(2)}$ of \mathbf{P}^2 is the conditional probability, given that the system is in E_i , that it will be in E_j two steps later. In the same way, the n th order transition probability $p_{ij}^{(n)}$, the conditional probability that the system will occupy E_j after n steps if it is now in E_i , is the (i, j) th entry in \mathbf{P}^n . But \mathbf{P} alone does not determine the absolute probability $a_i^{(n)}$ that at time n the system is in state E_i . For this we need \mathbf{P} and the initial probabilities $a_i^{(1)}$.

The probability that the system occupies states E_i and E_j respectively at times n and $n+1$ is

$a_i^{(n)} p_{ij}$; adding over the states possible at time n , we conclude that $\sum_i a_i^{(n)} p_{ij} = a_j^{(n+1)}$, or, if $\mathbf{a}^{(n)}$ denotes the row vector $(a_1^{(n)}, \dots, a_s^{(n)})$, $\mathbf{a}^{(n)} \mathbf{P} = \mathbf{a}^{(n+1)}$. More generally, the m th order transition probabilities link the absolute probabilities for time $n+m$ to those for time n : $\sum_i a_i^{(n)} p_{ij}^{(m)} = a_j^{(n+m)}$ or $\mathbf{a}^{(n)} \mathbf{P}^m = \mathbf{a}^{(n+m)}$. Thus the absolute probabilities $a_i^{(n)}$ are completely determined, via the relation $\mathbf{a}^{(n)} = \mathbf{a}^{(1)} \mathbf{P}^{n-1}$, by the transition probabilities p_{ij} and the initial probabilities $a_i^{(1)}$. In other words, \mathbf{P} and $\mathbf{a}^{(1)}$ completely specify the probability laws of the Markov chain.

Chains with all $p_{ij} > 0$. The most important mathematical results about Markov chains concern the stability of the $a_i^{(n)}$ and the behavior of $p_{ij}^{(n)}$ for large n . Although some of the p_{ij} may be zero, suppose they are all strictly greater than zero. (Later this restriction will be lifted and other chains considered.) One expects that for large n , $p_{ij}^{(n)}$ should not depend much on i —the effect of the initial state should wear off. This is indeed true: there exist positive numbers p_1, \dots, p_s such that $p_{ij}^{(n)}$ is close to p_j for large n ($\lim_{n \rightarrow \infty} p_{ij}^{(n)} = p_j$ for all i and j). It follows that $a_i^{(n)} = \sum_k a_k^{(1)} p_{ki}^{(n-1)}$ approaches $\sum_k a_k^{(1)} p_i = p_i$ as n becomes large, so that the absolute probabilities $a_i^{(n)}$ stabilize near the p_i , no matter what the initial probabilities $a_i^{(1)}$ are.

The numbers p_i have several important mathematical properties, which in turn have probability interpretations. Clearly they sum to one: $\sum_i p_i = 1$. Moreover, if n is large, $\sum_i p_{ij}^{(n)} p_{ij}$ is near $\sum_i p_i p_{ij}$, while $p_{ij}^{(n+1)}$ is near p_j . Since $\sum_i p_{ij}^{(n)} p_{ij} = p_{ij}^{(n+1)}$, we have $\sum_i p_i p_{ij} = p_j$, or, with $\mathbf{p} = (p_1, \dots, p_s)$, $\mathbf{pP} = \mathbf{p}$. Therefore the p_i solve the system

$$(1) \quad \begin{aligned} \sum_{i=1}^s p_i p_{ij} &= p_j, & j &= 1, 2, \dots, s, \\ \sum_{i=1}^s p_i &= 1 \end{aligned}$$

of $s+1$ equations in s unknowns. Since it turns out that this system has but one solution, the limits p_i can be found by solving it, and this is the method used in practice. The vector \mathbf{p} for the social mobility example is (.067, .624, .309). Whatever a man's class, there is probability near .309 that a descendant a great many generations later is in the lower class.

The quantities p_j connect up with the absolute probabilities $a_j^{(n)}$. If $\mathbf{a}^{(n)} = \mathbf{p}$, then $\mathbf{a}^{(n+1)} = \mathbf{a}^{(n)} \mathbf{P} = \mathbf{pP} = \mathbf{p}$, and similarly $\mathbf{a}^{(m)} = \mathbf{p}$ for all m beyond n . In other words, if the system has at a given time probability exactly p_j of being in state E_j (for each j) then the same holds ever after. For this reason, the p_j are called a set of *stationary probabilities*;

since the solution to (1) is unique, they form the only such set.

Thus a system evolving according to the laws of the Markov chain has long-range probability approximately p_i of being in E_i ; and if the probability of being in E_j at a particular time is exactly p_j , this relationship is preserved in the future. The law of large numbers gives a complementary way of interpreting these facts. Imagine a large number of systems evolving independently of one another, each according to the laws of a common Markov chain. No matter what the initial states of the many systems may be, after a long time the numbers of systems in the various states will become approximately proportional to the p_j . And once this state of affairs is achieved, it will persist, except for fluctuations that are proportionately small if the number of systems involved is large. In the social mobility example, the proportions in the three classes of a large number of family lines will eventually be nearly 067:624:309.

A system setting out from state E_i is certain to return again to E_i after one or more steps; the expected value of the number of steps until first return turns out to be $1/p_i$, a result that agrees qualitatively with intuition: the lower the probability of a state the longer the average time between successive passages through it. There exist also formulas for the expected number of steps to reach E_j for a system starting in E_i . In the example from mobility theory, the mean time to pass from the lower class to the upper class is 26.5 generations, while the mean for the return trip is but 5.6 generations (which should be a lesson to us all).

Other Markov chains. In the analysis sketched above, it was assumed that the p_{ij} were all strictly greater than zero. More generally, the same results hold even if some of the p_{ij} equal zero, provided the Markov chain has the property that the states all communicate (for each i and j there is an n for which $p_{ij}^{(n)} > 0$) and provided also that there is no periodicity (no integer m exceeding 1 exists such that a passage from E_i back to E_i is possible in n steps only if n is divisible by m). Such a chain is called ergodic. The results can also be reformulated to cover nonergodic chains.

The theory extends in still other useful ways. (a) A chance process is a Markov chain of second order if the probability distribution of future states depends only on the two most recently visited states: $P(E_i|E_j, E_k) = P(E_i|E_j, E_k)$, $P(E_m|E_i, E_j, E_k, E_l) = P(E_m|E_k, E_l)$, etc. These processes contain ordinary Markov chains as a special case and make possible

a more precise description of some phenomena. The properties derived above carry over to chains of second (and higher) order. (b) If, for instance, the system is a population and the state is its size, there are then infinitely many possible states. The theory generalizes to cover such examples, but the mathematics becomes more difficult; for example (1) becomes a system of infinitely many equations in infinitely many unknowns. (c) Continuous time, rather than time that goes in jumps, is appropriate for the description of some systems—for example, populations that change state (size) because of births and deaths that can occur at any instant of time. Such processes in principle admit an approximate description within the discrete-time theory: one observes the system periodically (every year or minute or microsecond) and ignores the state occupied at other time points. However, since such an analysis is often unnatural, an extensive theory of continuous-time processes has grown up.

Statistical analysis. One may believe a given process to be a Markov chain—or approximately a Markov chain—because of his knowledge of the underlying mechanism. Or he may hypothesize that it is a Markov chain, hoping to check this assumption against actual data. Under the Markov assumption, he may want to draw from actual data conclusions about the transition probabilities p_{ij} , which are the basic parameters of the model. In other words, statistical problems of estimation and hypothesis testing arise for Markov chains just as they do for independent processes [see ESTIMATION; HYPOTHESIS TESTING].

Suppose one observes n systems (governed by a common Markov chain), of which n_i start in state E_i , and follows each of them through one transition. If n_{ij} is the number that step from E_i to E_j , so that $\sum_j n_{ij} = n_i$, then the log-likelihood function is $\sum_{i,j} n_{ij} \log p_{ij}$; maximizing this function with the s constraints $\sum_j p_{ij} = 1$ gives the natural ratios n_{ij}/n_i as the maximum likelihood estimators of the p_{ij} . The numerical matrix given for the social mobility example was obtained in this way from a sample of some 3,500 father-son pairs in England and Wales. If the n_i are large, the estimators are approximately normally distributed about their mean values p_{ij} . By seeing how far the n_{ij}/n_i differ from putative transition probabilities p_{ij} , one can test the null hypothesis that these p_{ij} are the true parameter values. The statistic appropriate for this problem is $\sum_{i,j} (n_{ij} - n_i p_{ij})^2 / n_i p_{ij}$; it has approximately a chi-square distribution with $s(s-1)$ degrees of freedom if the n_i are large.

Other tests are possible if the systems under observation are traced for more than one step. Suppose n_{ijk} is the number of the systems that start in E_i , step to E_j , and then step to E_k . If the process is a Markov chain, then (a) the chance that the second step carries the system from E_j to E_k does not depend on the initial state E_i and (b) the transition probabilities for the second step are the same as those for the first.

Let a dot indicate an index that has been summed out; for example, $n_{.ij} = \sum_k n_{kij}$ is the number of systems that are in states E_i and E_j at times 2 and 3, respectively (with the state at time 1 completely unspecified). Assuming (a), one can test (b) by comparing the estimators $n_{ij.}/n_{i..}$ of the transition probabilities for the first step with the estimators $n_{.ij}/n_{.i.}$ of the transition probabilities for the second step. And one can test (a) itself by comparing the ratios $n_{.jk}/n_{.i.}$ (the estimated second-step transition probabilities) with the ratios $n_{ijk}/n_{.jk}$ (the estimated second-step transition probabilities, allowing for possible further influence of the initial state); if (a) holds, $n_{ijk}/n_{.jk}$ should, independently of i , be near $n_{.jk}/n_{.i.}$; thus one can check on the Markov chain assumption itself.

This statistical analysis, based on following a large number of independently evolving systems through a small number of steps, really falls under the classical chi-square and maximum likelihood theory. There is also a statistical theory for the opposite case, following a small number of systems (perhaps just one) through many steps. Although the estimates and tests for this case have forms similar to those for the first case, the derivation of their asymptotic properties is more involved.

The statistical analysis of Markov chains may be extended in various directions. For example, a mode of analysis in which *times of stay* in the states are considered, together with transition probabilities, is discussed by Weiss and Zelen (1965).

I FAMILY FORMATION

The beginning of family formation may be either marriage or parenthood. It should not be concluded from the fact that sexual intercourse is a prerequisite for pregnancy that all peoples regard marriage or the establishing of a man-woman relationship as the first step in family formation. Indeed, according to Bohannan (1963, p. 73) the matricentric family, consisting of a woman and her children, is "both more nearly universal and more elementary than is the nuclear family," consisting of a marital couple plus any children they may have. In some societies it is thought proper that marriage should precede pregnancy, while in others the reverse sequence is regarded with favor; in the extreme case marriage is viewed as irrelevant to family formation. However, it seems safe to assert that in most societies the nuclear family is thought to be well launched only when both conditions are met.

Cultures also vary according to whether they emphasize marital solidarity over lineal solidarity or vice versa. Societies with strongly developed extended family systems emphasize lineal solidarity over marital solidarity. In such societies family formation is scarcely a meaningful concept: since the marriage of a man and woman and the coming of their progeny represent the carrying on of a continuous line, these events may signal the establishing of a new household but not the formation of a new family.

In this article the topic of family formation will be treated with reference to the nuclear family. Marriage will therefore be considered as the focus of the process of family formation, and mate selection as one of its most problematic features.

Definitions. From the functional point of view, the family is the one social system that all societies look to for the replacement of their members. However, from the structural point of view, the word "family" is used to refer not only to the marital couple and their children but also to the larger kin group; accordingly, it will be necessary to draw some structural distinctions. The "extended family" includes a nuclear family plus lineal and collateral kinsmen; to the extent that a society emphasizes rights and obligations among kinsmen who are not in the same nuclear family, it is spoken of as having an "extended family system." On the other hand, a "nuclear family system" is said to exist in a society in which the rights and obligations among those in the larger kin group are given little emphasis relative to the claims among members of the same nuclear family.

It should be emphasized that the term "family," whether it applies to a nuclear or an extended family, is not equivalent to the term "household"—the aggregate of persons occupying a common dwelling unit, whether or not those persons are kinsmen. In Western societies the nuclear family is frequently also a household while the parental couples are in their younger and middle years and before their children attain adulthood. However, many other arrangements are possible, and some are institutionalized. For example, in South Africa it has been the practice for decades for the husband-father to be away from his nuclear family for years at a time. A common type of household among

Negroes in the Caribbean and in the United States consists of a working woman, her children, and her mother. In traditional China the ideal household included the nuclear family of the head of the household plus his unmarried daughters, his sons with their nuclear families, his sons' unmarried daughters, his sons' sons with their nuclear families, and so on through all living generations; in practice, however, not many Chinese families could afford households of such size.

Marriage may be defined as a culturally approved relationship of one man and one woman (monogamy), of one man and two or more women (polygyny), or of one woman and two or more men (polyandry), in which there is cultural endorsement of sexual intercourse between the marital partners of opposite sex and, generally, the expectation that children will be born of the relationship ("polygamy" is the term that subsumes both polygyny and polyandry). "Homogamy" refers to the marriage of persons of similar characteristics, which is also known as "assortative" or "assortive" mating; "heterogamy" is the marriage of persons of different characteristics; and "hypergamy" is a marriage in which the husband is of higher social status than the wife. The term "endogamy" refers to marriage between persons belonging to the same social group, whereas in "exogamy" the partners come from different groups.

Marriage and legitimacy. By definition marriage is a relationship within which sexual intercourse is legitimate. In general, a woman who cohabits with a man has a legitimate status in relation to that man only if she is known to be married to him. Common-law marriage (recognized in the United Kingdom and in the United States) and the consensual union (recognized in the Caribbean) are forms of man-woman relationship that carry less than full cultural approval and legitimacy. Points of interest to American, as well as to English, courts in establishing whether or not a common-law marriage exists include: mutual agreement of the man and woman to take each other as husband and wife; cohabitation and presentation of themselves as a married couple to friends, neighbors, and the general public; and reputation, that is, the recognition by the community that the two are husband and wife.

The Caribbean pattern of the consensual union differs from the common-law marriage of Anglo-Saxon countries in that the former is not a legally recognized marriage. Various writers have held that except for this lack of legal sanction the consensual union carries no social stigma and therefore is quite as acceptable among the people prac-

ticing it as is legal marriage. More recent analyses by Blake (1961) and by Goode (1960), however, have concluded that there is general recognition among Caribbean societies that consensual unions are less legitimate and hence less desirable than legal marriages. Goode argues that whereas legal marriage is recognized throughout Caribbean societies as the legitimate form, there is variation among the social strata of these societies in the degree of norm commitment, with the consequence that persons in the lower strata tend to be generally less committed to familial norms than persons in the upper strata. The more frequent occurrence of consensual unions among the lower social strata than among the upper is seen as a reflection of the class-linked variation in the degree of commitment to familial norms. [See CARIBBEAN SOCIETY.]

Legitimacy affects the offspring of the marriage as well as the spouses themselves. In asserting what he called the "principle of legitimacy," Malinowski (1929) stated that in all societies a socially recognized father has been regarded as indispensable to the child. A legal marriage, then, gives a woman a socially recognized husband and her children a socially recognized father. According to Zimmerman (1947), the penalties attached to illegitimacy vary directly with the power of the extended family; thus, the penalties are heavy in societies characterized by the extended-family system and light where the nuclear family prevails. From a sociological point of view, the significance of legitimacy is that it is a necessary condition for the family to carry out its function of position-conferring. In this sense, the critical meaning of bastardy is not that the child has *low* status but rather that he lacks *any* position and status in his society. [See ILLEGITIMACY.]

Variations in familial organization. Cultural expectations pertaining to marriage are affected by variations in familial organization. In Western civilization it appears that the power of the family and the size of the effective kin group (i.e., of the familial structure) have varied inversely with the complexity of the society of which the effective kin group is a part. Zimmerman (1947), who extensively analyzed the civilizations of ancient Athens and Rome, reports that in the early stages of both of these civilizations (i.e., when both societies were relatively simple) there existed what he calls the "trustee" type of familial organization; whereas in their late (and, to Zimmerman, decadent) stages, Athens and Rome developed much more complex societies and simpler familial structures, which he describes as "atomistic." The kernel of Zimmer-

man's distinction lies in the locus of power. Where the trustee type of family exists, much power is located in the extended family. The head of the family, as the responsible center of familial authority, influences the behavior of the family members, and the extended family feels responsible for the behavior of its members. Where the atomistic type of family prevails, much power is located outside the kin group in specialized institutions. As the family loses power, its structure shifts from the extended family system to the nuclear family system. In the process of making this shift, according to Zimmerman, the divorce rate goes up and the birth rate goes down. Arguing that there are other lines of development than those of the West noted by Zimmerman, Goode (1963) holds, as we shall see below, that whether the divorce rate goes up as a society becomes more complex depends on the nature of the familial structure at the start of the process.

One way of formulating variation in the family's power and size is to speak of its functioning as a political unit. Moreover, the family may show variation in other kinds of functioning. In some settings the family is the basic economic unit that creates and distributes goods and services. In many settings it is the principal social unit responsible for socializing and educating the young. And in some settings, especially where ancestor worship is practiced, the family carries out the religious function. In general, as societies become more complex, specialized societal structures develop for the carrying out of these functions, with the result that the family loses some of its functions; indeed such a state of affairs is the meaning of societal complexity.

Taking account of Asian and African as well as Western societies, Goode (1963) agrees that most family systems of the world are moving toward a small-family system based on the nuclear family. Because the traits of non-Western family systems are so varied, however, he believes there will be marked differences in the direction of this change as the predicted convergence takes place. Thus, in African tribal societies where matrilineal systems are strong and divorce is common, Goode reasons that urbanization will be accompanied by a reduction in the conditions that have made divorce easy.

Mate selection

The functional emphasis in modern sociology leads the observer to anticipate that criteria for the choice of a mate will be related to the roles the mate is expected to enact and, perhaps, that the mate will be chosen by the incumbent of that social position most influenced by the quality of the mate's

performance. There is some evidence to support such a set of functional expectations, but of course the empirical world is always less tidy than the social scientist's model.

The extended family system. In the extended family system it is common for members of the nuclear family to work in teams of kinsmen. Under this condition the mate-selective process is frequently a means of recruiting workers, and hence the members of the extended family have a lively interest in the work-related qualifications of a kinsman's prospective mate. Thus it is not unusual for responsible senior members of the extended family to select a son's spouse and to employ such family-relevant criteria as the industry and prospective fecundity of a potential daughter-in-law. For families of higher status, the standing of a girl's family becomes more important than her manual skills. Irrespective of status, however, the extended family system makes the procuring of a mate a matter of moment to a wide circle of kinsmen. It is consistent with this kind of family organization that mate selection should be a task calling for experienced perception and shrewd bargaining. Moreover, in order that their plans should not be thwarted by the passions of the young, the older people institute devices such as early marriage and efficient chaperonage (Goode 1959).

On the other hand, where the extended family is not highly functional and where the nuclear family system prevails, it is frequently thought to be inappropriate for members of the extended kin group to exhibit lively interest in the marital choices of family members, and even the influence of parents is reduced. Under these conditions the criteria for mate selection are more likely to include attributes having primary appeal to the nubile pair—physical beauty, sexual attractiveness, and congeniality. The response to one or more of these attributes comes to be subsumed under the rubric of love. The diminution of relatives' influence in mate selection is not, of course, a categorical matter but rather one of degree. By their own religion, ethnicity, and social status, as well as by their own choice of location of residence and of schools, parents continue to influence their youngsters' choice of spouses.

Traditional China provides an example of mate selection carried on by the family for familial purposes. When a son married, the preferred arrangement was for him to bring his bride into his parental home. The parents expected the bride to perform two important functions: to bear children, preferably sons, and to assist her mother-in-law in the performance of domestic chores. As the boy

4 MARRIAGE: Family Formation

was growing up, he looked to his parents to provide him with a wife. The parents expected the son to accept whatever bride they chose, and they condemned vigorously any disposition on the son's part to make his own marital selection, especially if the son tried to do so on the basis of love. It was generally agreed that young people of marriageable age were too inexperienced to have sound judgment in such an important undertaking. Since most of the bride's time was to be spent assisting her husband's mother, functional considerations dictated that the latter was the most interested party in the marriage; appropriately, therefore, she was usually the most active person in selecting her son's wife. Thus, arranged marriages were customary, and it was not unusual for a young man to meet his bride for the first time at the wedding ceremony. Traditional China made extensive use of the "go-between," or marriage broker. This occupation served two useful functions: marriage brokers made it their business to have extensive and detailed information about marriageable young people; and they made it possible for families to enter into and break off negotiations without loss of face (Hsu 1948; Lang 1946; Levy 1949).

With industrialization came pressure for changes in Chinese family law. This was evident as early as the Boxer Rebellion at the beginning of the twentieth century, and new codes were promulgated in 1930 and 1931 (well before the communist revolution in China) that reflected Western standards—more emphasis on the nuclear family and less on the extended family, a reduction in male authority, and a closer approximation to legal equality of the sexes. However, the law retained a feature of Chinese filial piety: the obligations to one's parents superseded the obligations to one's children. In these matters the communist revolution has represented not so much a break with the past as a continuation of trends already under way (Yang 1959). Although reliable information on postrevolutionary China is still scanty, it appears that whereas the communist regime officially deplores both Western and traditional Chinese ways, love marriages are common, and the influence of the extended family is continuing to wane.

The nuclear family system. As specialized social structures spring up, take over functions from the family, and become societally important and individually rewarding, the resulting reduction in the functional importance of the extended family removes incentives for maintaining an extended family system. At the same time there are four functions inherent in the nuclear family that come to the fore as being relevant in mate selection.

These functions are: providing emotional gratification in the marital and parental relationships; providing identity and a social status in the societal system to individuals who enter the family by birth, adoption, or marriage—a function to be known here as position-conferring; performing such tasks as cleaning, bringing in supplies, and disposing of waste products, which may be subsumed under maintenance of the household; and child rearing, especially with respect to the parental functions of nurturance and control.

Of these four functions emotional gratification is most explicitly recognized in American culture as relevant to mate selection, and apparently this is so, to an increasing degree, in the middle-class subcultures of western Europe. There can be little doubt that convictions are widespread in the United States and western Europe that a couple should be "in love" before considering marriage and that legal codes are obsolete if they fail to provide for divorce on the ground of chronic marital conflict. Love as a mate-selective criterion invites idiosyncratic interpretation in the sense that, for instance, one man may be attracted to a demurely diffident girl whereas another finds the vivaciously extroverted girl irresistible.

As a mate-selective criterion, position-conferring (especially when phrased as status-conferring) evokes ambivalent responses. In many middle-class settings a girl who is thought to have married for money rather than for love risks social condemnation (Indian culture, by contrast, has had the tradition that it is good for a girl to marry into a subcaste of higher standing than her own). If a girl marries for love *plus* status improvement, however, she is said to have married "well," and the durability of the Cinderella legend suggests that there is little novelty in this theme. The woman's social status depends so largely on her husband's occupational performance that, for her, mate selection is sometimes spoken of as a "mobility bet." Such evidence as exists on this matter for the United States indicates that most marriages are between persons of roughly equal social status.

Although all four of the functions mentioned above are relevant to mate selection, a young couple considering marriage can usually check the suitability of each other only with respect to emotional gratification. This may have something to do with the emphasis given love as a criterion. In the premarital setting of early adulthood the other three functions can usually be no more than the focuses of guesswork. It is difficult for a young woman to foresee how a particular man will fare in the occupational sweepstakes and in being a

model for their sons. Predictions are similarly difficult for the young man with respect to how a woman will manage their house and mother their children.

Where marriages are voluntary rather than arranged, there is need of some means for marriageable young men and women to meet and to select each other. The practice of dating is societally rational in the sense that it affords this opportunity. On the other hand, dating as a prelude to mate selection has been criticized on the ground that the leisure-time activities of dating fail to provide an adequate setting in which to test prospective spouses with respect to marital relevant criteria, especially with respect to the functions of household maintenance and child rearing.

In sum, a reduction of functions in the extended family is accompanied by a reduction in the rights and obligations among extended kin that constitute the extended family system. This reduction in the significance of blood relationships shifts the emphasis from the extended family to the nuclear family. Marital solidarity replaces cognatic (both lineal and collateral) solidarity, and love becomes a criterion of mate selection.

Principles of preferential mating

Let us designate as "ego" a person of reference, that is, a person from whose point of view we shall consider certain relationships. All societies designate categories of persons whom ego may not marry, and frequently there are additional categories of persons whom it would be regrettable, but not totally forbidden, for ego to marry. Usually there are implicit, if not explicit, categories of persons whom it would be desirable for ego to marry. These negative and positive expectations can be subsumed under the "principle of incest avoidance" and the "principle of ethnocentrism." We shall speak of the set of persons whom ego is permitted to marry in any given sociocultural setting as ego's field of eligible spouse candidates or, in shorter form, as ego's "field of eligibles." European social scientists use the term "isolate" to refer to the field of eligibles.

The principle of incest avoidance. Every society has a prohibition against incest, that is, against sexual relations between persons who are closely related. Although the precise relationships that are viewed as incestuous vary from one society to another, they regularly include the mother-son, the father-daughter, and the brother-sister relationships, that is, all heterosexual relationships within the nuclear family except, of course, the marital relationship. The principle of incest avoidance re-

fers to the set of prohibitions existing in every culture to prevent ego from marrying someone too close to him in the kinship system.

Just how the principle of incest avoidance works out varies from one setting to another. In traditional China it was prohibited for ego to marry anyone with the same surname, and in that populous land with few surnames this rule proscribed hundreds of thousands of otherwise eligible spouse candidates. In northern India there was a tradition that marriage was not possible with someone removed from ego by less than seven degrees on the father's side or less than five degrees on the mother's; a more common rule in India prohibits marriage between relatives linked to a common ancestor within five degrees on the father's side and three on the mother's (Goode 1963, p. 210). In some societies ego is encouraged to marry a cross-cousin (e.g., mother's brother's daughter) but prohibited from marrying a parallel cousin (e.g., mother's sister's daughter). Prior to 1793 it was illegal in Connecticut for ego to marry the sister of his deceased wife; but among the ancient Hebrews there was the custom of the levirate, by which a man was enjoined to marry the widow of his deceased brother if the brother had died without a son. The record shows a very few isolated cases where persons of opposite sex from the same nuclear family were permitted to marry. An example is the brother-sister marriage among the Ptolemies of ancient Egypt. Apparently the practice in these few exceptions functioned to keep power within ruling families. [See INCEST.]

Ethnocentrism and homogamy. Whereas the principle of incest avoidance prevents ego from marrying someone too close to him in the kinship system, the principle of ethnocentrism prevents his marrying someone too different from him with respect to a number of social characteristics. In other words, ethnocentrism is a force tending toward endogamous and homogamous marriages.

Sumner ([1906] 1959, chapter 1) used the term ethnocentrism to refer to the set of attitudes shared by members of a tribe or other social group to the effect that the members of that group and any others like them were seen as the center of the civilized world and had, therefore, the correct and desirable set of social characteristics. Thus, ethnocentric attitudes lead to the condemnation of outsiders to the degree that they are recognized as differing from one's group. The minimum degree of social distance on the Bogardus scale is indicated by an affirmative response to the query as to whether or not the respondent would be willing to accept a person with a specified characteristic to

close kinship by marriage. Traditionally, the castes of India have been endogamous, as have the subaltern categories of subcaste, section, and subsection. According to Kapadia ([1955] 1958, p. 118), these endogamous restrictions limited a Hindu's field of eligibles to 50 to 300 families. In 1949, however, the Hindu Marriages Validity Act stipulated that no marriage of Hindus could be invalidated because of caste or sect differences between the parties concerned. Expert opinion is divided as to the likelihood that caste endogamy will break down.

In accordance with the principle of ethnocentrism there is evidence that in American society ego tends to select a spouse similar to himself with respect to race, religio-ethnic identification, socioeconomic status, and other social characteristics. In the United States the most conspicuously homogamous dimension of mate selection is race. Interracial marriages are still prohibited by law in a number of the Southern states; moreover, even where such laws do not exist, or where they have been repealed, there is little evidence of enthusiasm for such marriages. Various studies have shown the proportion of racially heterogamous marriages to be under one per cent. [See ASSIMILATION.]

The second dimension of ethnocentric preference and prohibition is that of religio-ethnic identification, which includes cultural as well as religious elements. Classifying the 1957 population of the United States into the three major religious categories (Protestant, Catholic, and Jewish), the U.S. Bureau of the Census found that approximately 94 per cent of the married persons had spouses in the same religious categories as themselves. If religious endogamy had not been practiced, and if, therefore, matings had been entirely random with respect to religious affiliation, the proportion having spouses in the same religious category as themselves would have been about 56 per cent (Winch [1952] 1963, p. 331). There is evidence that in heterogeneous communities the probability that ego will marry outside his religious category is greater when his category constitutes a small proportion of the community rather than a large proportion. If the religious category has a highly distinctive ethnic identity (e.g., Catholics who are Spanish-speaking in an English-speaking community), the probability of ego's marrying endogamously is increased.

A third dimension of ethnocentric preference is that of socioeconomic status. Commonly used indexes of socioeconomic status are occupation, income, and number of years of schooling. Numerous studies have shown that people tend to select their spouses from their own socioeconomic strata

with respect to all three of these indexes (several are cited in Winch [1952] 1963, pp. 336-338). Other characteristics with respect to which people tend to mate homogamously are age, previous marital status, and location of residence. Systematic research supports the common observation that young people tend to select young mates and older people choose older spouses. No doubt it is partially because of this fact that there is a tendency for people to marry others who are like themselves with respect to previous marital status: divorced men tend to marry divorcees; single persons tend to marry those who have not previously been married; and widows and widowers tend to marry each other. Another common-sense observation that has been supported by research concerns residential propinquity: ego is more likely to marry someone living nearby than someone living far away (Winch [1952] 1963, pp. 322-324, 339-345).

Since people are not randomly distributed through communities but rather tend to live near and to work with others of similar social characteristics, one would expect mate selection to be somewhat homogamous, whether or not there are any sanctions enforcing endogamy. Of course there are sanctions of varying degrees of intensity: for example, in American culture sanctions are quite intense with respect to race, less so with respect to religion and socioeconomic status, and virtually nonexistent with respect to residential propinquity.

Homogamy may also be considered on a more psychological level. For example, there is evidence that spouses tend to resemble each other in level of intelligence, in values (e.g., religious and aesthetic), and in attitudes (e.g., toward birth control and toward communism). When spouses are tested by paper-and-pencil methods, they appear to resemble each other somewhat, but not greatly, with respect to traits of temperament and personality. However, data gathered by other methods, such as interviews and projective methods, lead to the contrary conclusion that, at least in such traits as dominance and dependence, spouses tend to be complementary rather than similar. At present this seeming paradox is unresolved, although the answer may be that the homogamy apparent in paper-and-pencil tests is an artifact resulting from the effort of people to represent themselves to be as attractive as possible—what is called the "social desirability" effect (Winch 1958; [1952] 1963, chapter 18).

Differentiation of sex roles

The simple fact that only women can bear children causes every society to recognize some differentiation between the behavior of men and of

women. Beyond the behavioral differences that are directly attributable to anatomy and physiology, however, cultures vary greatly in the degree to which they view human behavior as being properly sex differentiated.

From a study of 224 societies, Murdock (1937) has found that men tend to engage in such active and mobile tasks as hunting, fishing, trapping, and lumbering, whereas women tend to specialize in more sedentary but equally important tasks, such as gathering fuel and fruits and cooking and preserving meat and fish. More generally, it is possible to conceptualize two criteria that distinguish masculine from feminine tasks. Tasks assigned to men usually require physical exertion and strength, or spatial mobility and absence from home for considerable periods of time, or both. By contrast, feminine activities are typically less demanding of great strength, although perhaps requiring a considerable output of energy, and will involve only a few hours at a time away from home.

Analysis of these differences leads to the conclusion that the sharpness with which a culture distinguishes between masculine and feminine sex roles will be related to the importance it attaches to tasks requiring one or both of the two masculine task characteristics. Military activity is one obvious example that involves both of the masculine criteria; thus it is argued that a highly military-oriented culture will be one that draws a sharp distinction between properly masculine activities and those that are properly feminine. The converse inference is that to the degree that a society's important tasks do not call for either of the criteria distinguishing masculine activities, there will be no basis for developing highly differentiated sex roles. As nonhuman power has taken over most of the heavy tasks in the industrial societies, the proportion of the total labor force that is classified as "white collar" has greatly increased. And white-collar occupations, especially those not requiring travel, can be carried on as well by women as by men. Thus, if Western cultures have been "feminized" over the past century or so, as some writers have claimed, the present analysis would interpret such a trend as a consequence of the increased use of nonhuman power.

Sex dominance in the marital dyad. What are the conditions that result in the dominance of one spouse over the other? The opportunity for dominance exists in a dyad when resources desired by one member are controlled by the other, that is, when one is dependent upon the other. Resources may be viewed broadly to include both material goods, such as food, and intangibles, such as a compliment.

Where no organizational feature exists to determine otherwise, it appears that men have usually dominated women. The reasons for this originate in the two criteria differentiating masculine from feminine pursuits and in their anatomical and physiological bases. A woman with small children has greater need of a man to take care of her than the man has need of her. His care may be viewed as a resource, and by granting or withholding that resource, the man can dominate the woman. This is a state of affairs that has been remarked by social scientists from Aristotle through E. A. Ross and Willard Waller and is perhaps best known to contemporary readers under the rubric of the "principle of least interest": that is, the person in a relationship who has the least to lose through the termination of the relationship is in a position to demand more from others and thus to dominate them in exchange for his continued participation. Aside from this situation of unilateral dependence, other possibilities are mutual interdependence, where the resources are not available to either one unless they cooperate, and mutual independence, where each has control over his own resources.

With respect to organizational features, W. G. Sumner and A. G. Keller have remarked that where the bridal couple lives has bearing on which is the dominant sex and therefore that matrilocal marriage is a condition favorable to the relative standing of women. In traditional China, the favored pattern was patrilocal, and a wife was expected to obey her husband; masculine dominance was mitigated, however, in the case of adoptive marriage. According to this pattern, a man having no son might seek a young man (who was usually of somewhat lower social rank) to take the older man's family name, marry the older man's daughter, and live matrilocally.

Studies of marriage

During the second quarter of the twentieth century there was a good deal of concern about the state of the family in the Western world. There was evidence that divorce rates had risen, that the family had lost functions to other social structures, that the birth rate had fallen, that certain totalitarian regimes were trying to bring about the disintegration of the family, and that broken families were spawning delinquent children. Family disorganization was widely viewed as a social problem; probably for this reason, numerous studies were undertaken to discover the determinants, or at least some correlates, of what was variously called marital "adjustment," marital "happiness," and marital "success."

Although these studies did not undertake to dis-

tinguish very sharply among the three terms just noted, it does seem useful to differentiate them as follows. There are two kinds of marital adjustment, one pertaining to the role and the other to the psyche of the performer. An actor is adjusted to a marital or any other kind of role to the degree that he knows the expectations that define the role and, under the appropriate conditions, can produce the behaviors expected. On the other hand, he is adjusted psychically to the degree that the energy he invests in the role performance is commensurate with the gratification derived from it. Marital "happiness" refers to the subjective response of the actor to marriage and thus is related to psychic adjustment; however, one can be psychically adjusted when both output of energy and input of gratification are low, whereas presumably happiness requires at least a moderately high level of gratification. The term marital "success" implies the existence of a goal of marriage, and whatever goals there may be—avoidance of divorce, procreation, personality development of the spouses—seem to be more clearly conceived by those who write about marriage than by the participants whose behavior the writers describe.

Much of the research on marriage has been concerned with marital adjustment—that is, both with the aptitude to carry out the marital role and with the capacity to derive commensurate gratification from the performance. Kirkpatrick has surveyed a large number of studies and has reported the variables he finds that have correlated most consistently with what is here called marital adjustment. He has divided these variables into two sets: those that were clearly operating before the marriage and those that may or may not have been. Presumably the determinants of marital adjustment are more likely to come from the former set. Kirkpatrick ([1955] 1963, p. 389) presents the following premarital factors as having shown the strongest and most consistent association with high marital adjustment: happiness of parents' marriage; adequate length of acquaintance, courtship, and engagement; adequate sex information in childhood; personal happiness in childhood; approval of the marriage by parents and others; adjustment in engagement and normal motivation toward marriage; ethnic and religious similarity of the spouses; high social and educational status; maturity (marriage in the late twenties rather than in the teens or early twenties); similar chronological age of the spouses; and harmonious affection with parents during childhood.

Factors that may have become operative during marriage, rather than before, and therefore are regarded as part of the complex of marital adjust-

ment rather than among its determinants are early and adequate orgasm capacity, especially of the wife; confidence in the spouse's affection and satisfaction with degree of affection shown; equalitarian rather than patriarchal marital relations, with special reference to the role of husband; mental and physical health; and harmonious companionship based on common interests and accompanied by a favorable attitude toward the marriage and the spouse (Kirkpatrick [1955] 1963, p. 394).

COMPARATIVE ANALYSIS

Every society has rules governing the assumption of the conjugal roles of husband and wife; there are also discernible rights accruing to and obligations incumbent upon the individuals who assume

these roles. Marriage in all societies thus brings about a change in the jural status of the parties to the contract. Where marriage is defined by the state, it is possible to describe most of its jural entailments by reference to one or more legal codes adopted by that state. However, among many of the peoples studied by anthropologists, the jural tenets governing marriage cannot be ascertained by reference to codes laid down by a state and hence must be derived from the study of the recurrent patterns of behavior and of folk models that prescribe ideal behavior.

Marriage entails not only a change in the jural status of the individuals who enter the roles of husband and wife but also a change in the lawful status of specifiable consanguineal kinsmen of the individual partners. In fact, it is the linkage of groups as well as of individuals that is crucial to the formulation of the difference between marriage and its social analogues. Only marriage creates (or maintains) affinal relationships between the kinsmen of individuals who claim the roles of husband and wife (see Fortes 1959, p. 209). Even where it is socially admissible for individuals to *presume* conjugal status—that is, where they may assume the husband-wife roles without their actions being legitimated according to prevailing jural rules—this presumption of status does not generate lawful relations of affinity between kinsmen of the “spouses” concerned.

The importance of affinity to an understanding of marriage is made clear through a consideration of the nature of kinship. The social relations subsumed under the concept of kinship are of two fundamental types which, though referable to the biological processes of heterosexual mating and procreation, cannot be reduced to biology. Those social relationships based on parenthood and descent or, more precisely, on parenthood and filiation, are generally termed consanguineal relationships. All persons related by socially defined direct or shared descent are consanguineal kinsmen (P. Bohannan 1963, chapter 4). These “blood relatives” are distinguished in all societies from affinal relatives, i.e., those whose kinship status is fundamentally grounded “in law.” Human mating is everywhere socially regulated, and adult mating for the purpose of procreation is normally preceded by the creation of *jurally derived kinship ties* between the mating pair and between certain of their respective consanguineal relatives. The continuance of publicly acknowledged affinal kinship depends on adherence to prescriptions and proscriptions delimited by the particular society under consideration. Whereas many societies make no provision for the legal severance of consanguineal

kinship bonds, they all provide for the severance—“by law”—of those which are based “in law.”

Societies differ considerably with respect to the rules governing the way in which the roles of husband and wife should be assumed, with respect to the specific rights and obligations which accrue to persons in these roles, and with regard to the behavioral and jural attributes of the other affinal roles created by marriage. Nonetheless, most anthropologists have regarded the institution of marriage as a universal in human societies, and many have attempted to provide definitions of marriage sufficiently general to encompass its various manifestations.

The fact that marriage is closely linked to parenthood has led many scholars, including Westermarck, Malinowski, and Radcliffe-Brown, to propose definitions of marriage which center on what Malinowski termed “the principle of legitimacy.” Thus, Radcliffe-Brown writes: “Marriage is a social arrangement by which a child is given a legitimate position in the society, determined by parenthood in the social sense” (1950, p. 5). The general, though by no means universal, acceptance of this formulation is indicated by the fact that *Notes and Queries on Anthropology* defines marriage in an essentially similar, but by implication more limited, manner: “Marriage is a union between a man and a woman such that children born to the woman are the recognized legitimate offspring of both partners” (British Association for the Advancement of Science 1951, p. 110).

Edmund R. Leach was among the first to argue that a definition of marriage in terms of legitimacy is too limited. In his opinion, any attempt at a universal definition of marriage is inevitably “vain,” since the “institutions commonly classed as marriage are concerned with the allocation of a number of distinguishable classes of rights” (1961a, p. 107). Leach suggests that in most cases the institution of marriage serves to allocate rights to either or both spouses; in some cases it serves primarily to allocate rights to the husband and his wife’s brothers.

Despite Leach’s arguments against a universal definition of marriage, his formulations stimulated two fresh attempts at universal definitions. Prince Peter of Denmark suggested that in light of Leach’s propositions, marriage should be defined as “the socially recognized assumption by man and woman of the kinship status of husband and wife” (Peter, Prince of Denmark 1956). The task of the anthropologist would then be to ascertain and delineate the particular rights and obligations associated with these kinship roles in the particular societies being studied.

H. Fischer (1956) called this definition tautological, on the grounds that the Oxford and Webster dictionaries defined "husband" and "wife" respectively by phrases such as "a married man" and "a married woman." In a discussion of Nayar marriage, Gough agrees and reaffirms the heuristic value of a definition of marriage based on "the principle of legitimacy." In an attempt to overcome the difficulties inherent in any formulation which defines marriage as a union of "a man and a woman," and in an attempt to provide a substantive definition for the concept of legitimacy, Gough suggests that marriage be defined as "a relationship established between a woman and one or more other persons, which provides that a child born to the woman under circumstances not prohibited by the rules of the relationship is accorded full birth-status rights common to normal members of his society or social stratum" (1959, p. 32).

Her effort to refine the older, more general "principle of legitimacy" definition has yielded one which, on close examination, is equally inadequate. Operating with such a definition, no investigator could classify as married any particular woman who had assumed the jurally recognized kinship role of wife but who had not borne children. Of course, the conditions under which a child would be accorded "full birth-status rights" could be elicited by the investigator. However, for any given case, the researcher would have to await the birth—or perhaps the conception—of a child before he could ascertain whether conditions entailed in the husband-wife relationship had been violated. Furthermore, Gough's definition implies that in any society each person having "full birth-status rights" is the child of a relationship which can be termed marriage. Among various peoples of the world, "full birth-status rights" accrue to persons born of relationships which are not recognized as marriage according to prevailing jurial rules.

If a universal definition of marriage is to be formulated, it would seem that the one proposed by Prince Peter should serve as a model. Fischer's criticism of Prince Peter's definition may be disregarded, since dictionary definitions are usually unsatisfactory bases for discussions of roles. The roles of husband and wife must be defined in terms of the essential rights and obligations and the behavioral attributes entailed in them in any particular society. Gough and Fischer are justified in their concern that confronted with different forms of mating, the anthropologist employing Prince Peter's definition would be unable to decide which institutions should be referred to as "marriage," as "concubinage," etc. However, if the statement were

modified so as to define marriage as the *jurally valid and socially (or publicly) recognized* assumption of the kinship roles of husband and wife, there would be few or no problems concerning the distinction between marriage and its socially recognized alternatives. Such a proviso emphasizes that the publicly acknowledged kinship roles created by marriage—as opposed to its alternatives—derive support from the juridico-political domain of the society. Of course, there may be more than one jurally valid way of assuming the roles of husband and wife—as is the case in some present-day African states which recognize marriages contracted according to one or more sets of "customary laws" as well as marriages contracted in accordance with legal codes based on European models.

It would appear that the cross-cultural study of marriage must rest on the premise that all societies recognize kinship roles which are founded "in law" as well as those which are based ultimately on actual, assumed, or presumed genetic relationships. Fundamental to the understanding of the concept of "lawfully based" kinship is the fact that human mating is everywhere subject to socially derived regulations. While it is normally expected that marriage will lead to parenthood, the roles of husband and wife need not be defined by reference to children who will come to be regarded as legitimate offspring of individuals in these roles. The roles of husband and wife should be defined in terms of the rights and obligations which attach to them, and marriage must be defined as the lawfully or jurally recognized assumption of these roles.

Choice of spouses

In all societies, socially derived limitations are placed on the range of persons from among whom spouses may be chosen. Regulations which prescribe marriage outside a stipulated group are referred to as *rules of exogamy*. Kin groups such as lineages, or territorial groups such as bands or villages, may constitute exogamous units. Societies possessing corporate unilineal descent groups usually prescribe that a person select as spouse someone from a descent group other than his own. In some cases the selection may be made from among persons within the descent group but outside specified degrees of relationship. Among the Gisu of east Africa, for example, it is the minimal patrilineage, comprising persons who trace their descent from an ancestor three to five generations removed from the oldest living generation, which constitutes the exogamous unit.

Every society prohibits heterosexual mating between certain "close" consanguineal relatives. This

prohibition is referred to as the *incest taboo*, and ordinarily it proscribes mating between relatives who stand to each other in the relationships of mother and son, father and daughter, and brother and sister. In many societies the incest taboo is extended to various other kinsmen in the parental and filial generations. Among some royal or ruling groups, as in dynastic Egypt and in Polynesia, relatives ordinarily prohibited from mating may be preferred as marriage partners. The mating of close relatives is also permitted in some societies on specified ritual occasions.

A rule of *endogamy* exists where the field of possible spouses is limited to persons within an individual's territorial and/or social group. The castes of traditional India are the most often cited example of endogamous groups. Other societies also prescribe marriage among persons of the same social stratum. Among the Swazi of south Africa, where lineage exogamy prevails and where royalty marries royalty, there are frequent subdivisions of the royal lineage so as to make possible otherwise prohibited marriages. A number of studies indicate that in the absence of explicit prescriptions, it is possible to discover endogamous tendencies within social or territorial groups of various size and scale.

In addition to proscriptions associated with incest and exogamy, societies usually prohibit marriage between certain other categories of persons. In some instances slaves cannot marry freemen. Where age sets are a feature of social organization, as among the Nuer, a man may be prohibited from marrying the daughter of another man in his age set.

Societies which prescribe that a spouse be chosen from among one or more designated categories of persons have been said to possess *closed marriage systems*. Those in which such prescriptions do not exist have been characterized as having *open marriage systems*. The designation of a marriage system as "closed" is not meant to suggest total absence of choice in the process of mate selection. This point is illustrated by Klass (1966), who shows that in Bengal (and in other parts of India), while caste affiliation delimits the broad category of persons from which a spouse is chosen, a man who must choose husbands for his daughters or "wards" does so from within a relatively narrow selection of eligible males known to certain of his kinsmen.

The most frequently cited closed marriage systems are found among the indigenous societies of Australia. Some of these societies, for example the Kariera, practice what anthropologists term "symmetrical cross-cousin marriage," wherein pairs of

local groups engage in the "simultaneous or nearly simultaneous exchange of women" (Leach 1961a, p. 59). The male members of the two groups concerned exchange their "sisters" for "wives." Ideally, a male ego marries his mother's brother's daughter, who may at the same time be his father's sister's daughter and the sister of his own sister's husband.

Among the Murngin of Australia is found a type of asymmetrical cross-cousin marriage wherein marriage with the mother's brother's daughter is preferred and marriage with the father's sister's daughter is proscribed. In this society and others practicing matrilineal cross-cousin marriage, a localized descent group gives wives to one or more other such groups and receives wives from a different set of such groups. In Murngin society there are descent groups which are allied through ties of kinship and ritual. Moreover, each pair of such allied groups stands in balanced opposition to another similar pair with which it exchanges women on a *nonexclusive* basis. Since men do not marry within their own moiety, any male ego and his mother's brother are in opposite moieties. Ego's group receives wives from and gives prestations to his mother's brother's group. Ego's mother's brother's group receives wives from and gives prestations to the group with which ego's group is allied. This latter group is the one containing ego's mother's mother's brother, who, of course, stands in the relationship of mother's brother to ego's own mother's brother. It can be said, therefore, that in Murngin society the "mothers' brothers" stand in the relation of "wife givers" to their sisters' sons (see Leach 1961a, pp. 68-72).

Claude Lévi-Strauss, Edmund R. Leach, Louis Dumont, and others have discussed the economic and political implications of this and other forms of "cousin marriage." Leach (1961a, pp. 54-104) has shown that where matrilineal cross-cousin marriage prevails, there exist permanent status differences between wife-giving and wife-receiving groups and has demonstrated that the marriage system is not insulated from other domains in the society. In fact, he argues that marriage alliance in such situations is but one of "many continuing relationships between paired local descent groups." Political and economic relationships are reflected in and sustained by the system of matrilineal cross-cousin marriage.

In open marriage systems, the only group of persons unequivocally proscribed as marriage partners are those to whom the incest taboo is extended. There are no normative prescriptions relating to groups from which spouses should be chosen. Nonetheless, many studies indicate that demo-

graphic, ecological, and sociological factors enter into the choice of spouse. Age, residential propinquity, class, religion, ethnicity, education, and occupation have been isolated as important determinants in the choice of marital partners. Likewise, parents and peer groups are often instrumental in delimiting for each individual the field from which a spouse will be chosen.

The transfer of rights at marriage

Marriage involves the allocation of rights and obligations among the parties to the agreement. A number of anthropologists have attempted to classify the various rights which are known to be allocated at marriage in different societies.

In discussing the jural element in marital and other kinship relations, Radcliffe-Brown (1950, p. 12) distinguishes personal rights (*jus in personam*) from possessive rights (*jus in rem*). A right *in personam* confers on an individual or a group the power to order the performance of certain duties by another individual or group. Rights *in rem* constitute claims on an object or person such that any encroachment on the object or person constitutes a violation of the "possessor's" rights. In most societies husbands and wives have personal rights in each other: either spouse may claim certain duties of the other. It is also common to find that a husband has "possessive" rights in relation to his wife. Her seduction, her abduction, or her murder would constitute a serious infringement of her husband's rights.

In an important contribution to the literature on marriage, Laura Bohannan (1949) distinguishes two classes of rights in females which may be allocated at marriage. Rights *in uxorem* (rights in a woman as wife) are distinguished from rights *in genetricem* (rights in a woman as mother).

In her discussion of Dahomean marriage, Bohannan shows that rights over a woman's sexual powers and certain of her domestic services were transferred from a woman's patrilineage to the man or woman who made the appropriate bride-wealth payments. In most of the "types" of Dahomean marriage, rights to any children a woman might bear during the course of her marriage were also transferred from a woman's patrilineage to that of her husband. Distinct classes of marriage payments were necessary to the transfer of each of these two classes of rights. However, in certain "types" of marriage, rights *in genetricem* were retained by the woman's natal patrilineage; this might occur in cases where a lineage was faced with a shortage of male heirs and one of the daughters of the lineage was given in marriage to

a man who agreed to make all the bride-wealth payments except those which would have given him jural authority over children of the marriage. Moreover, the marriage of a woman of the royal lineage never involved the transfer of rights *in genetricem* to the lineage of her husband (L. Bohannan 1949).

Even though it is usually rights in women which are in the forefront of marital negotiations, Leach has pointed out that marriages also serve to allocate rights in and over men (1961a, pp. 107-108). He suggests that a marriage may serve to do the following:

- (1) To establish the legal father of a woman's children.
- (2) To establish the legal mother of a man's children.
- (3) To give the husband a monopoly of the wife's sexuality.
- (4) To give the wife a monopoly of the husband's sexuality.
- (5) To give the husband partial or monopolistic rights to the wife's domestic and other labor services.
- (6) To give the wife partial or monopolistic rights to the husband's labor services.
- (7) To give the husband partial or total rights over property belonging or potentially accruing to the wife.
- (8) To give the wife partial or total rights over property belonging or potentially accruing to the husband.
- (9) To establish a joint fund of property—a partnership—for the benefit of the children of the marriage.
- (10) To establish a socially significant "relationship of affinity" between the husband and his wife's brothers.

Leach thus focuses attention on rights in and regarding children, sexuality, domestic and economic services, and property. In the last instance, he suggests that marriages may establish between groups of men mutual interdependencies which could entail any of the above rights as well as others of a political nature.

Where there are corporate kin groups, the allocation of rights at marriage is usually effected by and between at least two such groups. In the case of first marriages, it is usual that the groups into which the husband and wife were born are parties in this rearrangement of social relations.

Where recruitment to the corporate kin groups is based on patrilineal descent, normally the rights over a woman's sexuality and procreative capacities that are held by her natal group are transferred

at marriage to the groom and his natal group. Thus, whereas prior to marriage any sexual offense against a woman constitutes a violation of rights held by her kin group, after marriage such an offense is an infringement of the groom's rights. Similarly, whereas children born to a woman outside marriage would fall under the jural authority of her natal kin group, those born after marriage are subject to the authority of, and have rights in, the groom's kin group.

Total rights over the bride's domestic and economic services are seldom transferred from her natal group to her husband or his kin group. The woman herself, as an adult member of the society, may retain some control over the dispensing of these services. Often her kin group retains the right to call upon these services. Among the Yoruba of Nigeria, for example, rights in the bride's sexuality, rights over her procreative powers, and partial rights over her domestic services are acquired at marriage by the groom and his patrilineage. However, a woman maintains control over her economic powers and resources, and her natal lineage retains the right to call upon her domestic services in certain circumstances. She is called upon to buy and prepare food at times when deities associated with her lineage must be propitiated, and on the death of a member of her lineage, she is expected to be of service in various ways.

This raises another point: in most societies possessing corporate patrilineages, a married woman does not usually relinquish all her rights in her natal lineage. She may retain some proprietary rights therein, and she usually remains under the religious protection of her lineage ancestors. Moreover, a woman's lineage may have the right to reclaim control over her sexual and procreative powers should there be a breach of the marital agreement on the part of her husband. While these statements are generally true, there are some patrilineal societies in which a married woman becomes virtually "absorbed" into her husband's lineage. According to Gluckman (1950), a married woman among the Zulu of south Africa had virtually no rights outside her husband's lineage; once a woman was married, her natal lineage forfeited virtually all authority over her.

Whatever rights are transferred to the husband or his lineage may be temporarily or permanently reallocated by him or his lineage. The most common example of this is the practice of "wife-lending" found among the Kipsigis and others. The fact that a man may permit another to have access to his wife's sexuality is proof of his monopoly over her sexual capacities. In some societies, a man

who is impotent may choose a sexual partner for his wife in order that she may bear children. Where this is so, the husband is the lawful father of the children, even though he is not the genitor. Where a female is permitted to assume the role of husband, she bestows her rights of sexual access to her wife on a man of her own or of her wife's choice.

In matrilineal societies, rights over the procreative capacities of women are held in perpetuity by their kin groups while partial or total rights in their sexuality are transferred at marriage to their husbands. Customarily, the husbands also attain rights to the domestic services of their wives. Among the Bemba of east central Africa, for example, a husband has monopoly over his wife's sexuality, but the children of any marriage belong to their mother's matrilineage and are therefore under the jural authority of the adult males of that group. A wife keeps her husband's house and contributes her labor to his agricultural pursuits.

Marriages and the exchanges of goods and/or services occasioned thereby are sometimes processual events extending over considerable periods of time. The rights and obligations entailed in the marriage may be allocated in serial fashion, the timing of their transfer being dependent on the transfer of the appropriate goods and services. In such cases, the exchange of goods and services may commence during the period of betrothal and continue even after the formal transfer of certain rights has taken place.

Where goods and services are exchanged as part of the marriage procedure, certain of these may be regarded as necessary prestations without whose exchange a transfer of rights will not take place. Others are contingent prestations which, although part of the contract, are not essential to the exchange of jural authority and the assumption of marital rights and obligations. As Fortes says, they constitute the "means of winning and preserving the goodwill of those with the power to transfer marital rights" (1962, p. 10).

The most general terms used to describe prestations entailed in the marital contract are those of *bridewealth* (or bride-price) and *dowry*. The former refers to gifts presented by the groom's kin group to that of the bride, and the latter describes gifts made by the bride's kin group to that of the groom. The dowry is the more familiar to Westerners, since for centuries it has been a part of the marriage contract in Europe. However, both *bridewealth* and *dowry* have been reported for various parts of the world.

Throughout history, the transfer of rights at

marriage has been enshrined in ritual and ceremony. This is a correlate of the fact that marriage transactions are always "publicly" acknowledged. The ceremonies which take place in effect call forth "the public" to bear witness to the lawfulness of the transactions. The sanctions which emanate from the jural domain of the society are strengthened by the incorporation of rituals associated with the religious realm of the society.

Concurrent marriages. The transfer of rights at marriage and the rituals associated with this transfer signify the assumption of new roles by the parties involved. In societies which permit *polygyny* or *polyandry*—marriages entailing a plurality of wives or of husbands, respectively—one of the partners to a marriage assumes the role of co-wife or co-husband along with the role of husband or wife.

In polygynous marriages, the husband usually acquires the same categories of rights in each of his wives. In patrilineal societies, a man is the legitimate father of all his wives' children, even though his rights over the wives' sexuality may be assigned to or "usurped by" other men. The children of polygynous marriages may or may not have equal claims on their father's property. In any case, each wife considers herself the guardian of her children's rights within the family created by the polygynous marriage.

Where polyandry is practiced, by definition a man does not have exclusive rights in his wife's sexuality. He may or may not have claims over the children which she bears him. Among the Sinhalese, rights over the wife's sexuality are partially vested in the first husband. The sexual rights of the other husbands are exercised with the consent of the first husband and the wife. A husband has claims over those of the wife's children whom he has fathered, and the children have legitimate claims over the property of their respective fathers. All the children have equal claims to the properties owned by their mother.

Among the Nayar of south India, a ritual marriage ceremony, called the *tāli* rite, bestowed upon a group of men of appropriate caste the right of access to a woman's sexuality. The completion of the *tāli* rite marked a girl's transition to womanhood. Thereafter, when she attained appropriate age, she could begin to enter into relationships, termed *sambandham* unions, with a number of men, for whom she might bear children. Rights over a Nayar woman's procreative powers were retained by her matrilineage, which had jural authority over her children. Nonetheless, in order for a child to have "full birth-status rights" in his

mother's lineage, he had to have an acknowledged father. A man acknowledged the paternity of a child by bearing certain expenses associated with its delivery. This man could be any one of those with whom the mother had entered into a *sambandham* union. In cases of doubtful paternity, a woman's current "visiting husband" could be forced by an assembly of persons in the neighborhood to make the birth payments. "But if no man of appropriate rank could be cited as potential father, woman and child were expelled from their lineage and caste" (Gough 1959, p. 30).

The levirate and the sororate. In many societies, an individual may assume the role of husband or wife in order to secure rights for a kinsman. Where the "true" *levirate* prevails, upon the death of a husband, it is the duty of one of his brothers to marry the widow, and any children born to the union are counted as the progeny of the deceased man. Certain of the "ghost marriages" found among the Nuer resemble the levirate. A man could marry a woman "to the name of" a brother who died childless, and the offspring of the union would be designated as children of the deceased. These practices differ from the custom of adelphic widow inheritance, wherein a man marries his deceased brother's widow and bears children who are counted as his own. Where the "true" *sororate* prevails, the husband of a barren woman marries her sister, and at least some of the children born to the union are counted as those of the childless wife. The term "sororate" is also used in reference to the custom whereby, upon the death of a wife, her kin supply a sister as wife for the widower. In the latter case, however, any children born to the woman are recognized as her own.

Affinal relationships. The transfer of rights at marriage not only signals the couple's assumption of new conjugal roles but also serves to establish or perpetuate affinal relationships between consanguineal kinsmen of the spouses. Often associated with affinal roles are behavioral attributes commonly subsumed under the categories of "joking relationships" and "avoidance relationships." Radcliffe-Brown (1952, pp. 90–116) has argued that the respect implied in avoidance practices and the formalized disrespect demonstrated by joking relationships are expressions of alliance or consociation. The actors in roles characterized by joking or by avoidance have divergent interests which could generate conflict between them and thereby undermine the bases of their common interests. The institutionalization of avoidance and joking serves to minimize the chance of the development of openly hostile relations between the parties.

The most widespread of the avoidance practices are those which restrict contact between a husband or wife and the mother-in-law and/or father-in-law. Such restrictions on contact may also extend to actual or classificatory brothers or sisters of the father-in-law or mother-in-law. Among the patrilineal Swazi of south Africa, a wife is prohibited from coming into face-to-face contact with her husband's father and those of his male relatives of the same generation resident in the compound. A man behaves in similar fashion toward his mother-in-law, but the likelihood of such contact is minimized by their residence in different compounds and often in different villages.

Joking relationships most commonly exist between a man or woman and affinal relatives of opposite sex in the spouse's generation. These relationships are characterized by the use of intimate names, the use of language otherwise considered lewd or abusive, and, in some cases, by indulgence in sexual play.

Affinal relatives are often expected to give assistance to one another in times of exigency. In many societies where political functions are vested in roles defined primarily by kinship criteria, affinal relatives serve to minimize open conflict between their respective consanguineal kin groups. They might serve, as among the Tiv of Nigeria, as emissaries of peace in cases of latent or open conflict between two lineages.

The linkage of individuals through marriage leads to the creation of new groups or, in Nadel's terminology, to the creation of new sets of bounded social relationships and thereby constitutes a phase in the developmental cycle of kin groups. As Radcliffe-Brown has pointed out, the eventual result of most marriages is that new sets of individuals are linked through common descendants.

Ultimately, the fission of kin groups can often be traced to relations generated by marriage. This process is evident in many societies where lineages (or, for that matter, *ramages*) are a feature of social organization. When adult members of a lineage segment occupy a common residence along with their spouses and children, the process of incorporation of additional coresidents through marriage often eventually leads to the founding of households in other locations. In the course of time, the founders of such households and their descendants may come to form new lineage segments.

Postmarital residence

In some societies, spouses are expected to live together throughout the period of their marriage; in

others, they may be members of separate domestic groups and only visit each other's residences.

The "residence rules" outlined by anthropologists refer to situations in which husbands and wives are members of the same domestic unit. *Neolocal* residence predominates when couples establish independent domestic units after marriage. Residence is characterized as *virilocal* when most couples in a society join a domestic group in which the husband resided prior to marriage or in which he rather than the wife has proprietary or other claims. Residence is called *uxorilocal* when couples join the domestic group to which the wife was attached prior to the marriage or in which the wife rather than the husband has claims. The above terms may be compounded with others to describe more precisely the nature of the domestic group joined by the couple. Thus, *viripatrilocal* residence refers to domicile in a domestic group whose core includes the groom's father. *Uxorimatrilocal* residence refers to domicile in a group whose core includes the bride's mother. The term *avunculocal* is used to describe residence in a group whose core includes the groom's mother's brother.

Data collected by Goodenough (1956) and J. L. Fischer (1958) among the Nakanai of New Britain show that the classification of postmarital residence patterns is not as straightforward as some might assume. Their data also illustrate that there is no simple correlation between particular residence rules and particular rules for recruitment to descent groups. Goodenough shows that in this matrilineal society, a man takes his bride to live in the village in which his father resides. The couple lives there so long as the groom's father is alive, and they may remain after the father's death, particularly if the father is without sisters' sons who would be his jural heirs. More often, however, after the father's death, the couple moves to the residence of the husband's matrilineage, in which he has hereditary land rights. A man whose father is deceased takes his bride to live with the group which includes the man who acted as father-surrogate at the time of the marriage. Goodenough shows that even where ideal residence patterns suggest one or more prevailing modes of residence, the actual choices which couples make may depend on economic and other factors.

Fischer, who also worked on the island of Truk and who arrived at a classification of residences significantly different from Goodenough's, has suggested that residence be elicited for individuals than rather for married couples. He suggests that every person in a household has a "kin sponsor"

and that his relationship to this sponsor most appropriately describes the residence pattern for that individual.

While Fischer's suggestion has some merit for the classification of residence patterns for entire populations, attention cannot be shifted from the fact that in most societies the major spatial arrangements of individuals are associated with marriage. Moreover, the kinds of rearrangements which do occur have important implications for many kinds of social relations. It has been shown, for example, that the study of the developmental cycle of domestic groups touches on virtually all aspects of social structure and that postmarital residence patterns are crucial to the understanding of the development of domestic groups (Goody 1958).

Alternatives to marriage

Marriage is a process or event signifying the assumption of the roles of husband and wife in accordance with jural tenets prevalent in the society or stratum of society to which the parties belong. In contemporary societies, marriages are contracts which must be formally legitimized by the state. A state may provide that for purposes of inheritance, or for other specified purposes, persons who are not legally married to each other but who share a common domicile and who otherwise demonstrate a claim to conjugal status may be accorded some or all rights associated with legal marriage. Similarly, a state may choose to recognize marriages contracted according to rules formulated prior to its existence by some or all of the groups which constitute it. Such is the case in various parts of the world where formerly autonomous or semiautonomous political entities have come together to form modern nation-states.

Unions other than lawful marriage are known to have existed in stateless societies as well as in states which did not make the legitimization of marriages their official concern. Yet it seems particularly characteristic of modern societies that there are individuals who, for various reasons, assume some or all of the obligations and rights associated with the roles of husband and wife without entering into legal marriage. Reference has already been made to the fact that one of the crucial ways in which such unions differ from marriage is that they do not create lawful kinship ties between consanguineal relatives of the couple.

These "consensual unions" occur in different frequencies in different modern societies. In the United States, in the Caribbean, and in other areas where such unions occur with relatively high fre-

quency among certain socioeconomic classes and/or ethnic groups, research has centered primarily on family organization, and consensual unions are often regarded as but one aspect of over-all "family instability." The result is that while many hypotheses have been offered to account for the matrifocal or matricentric family which, in some areas, is one structural correlate of consensual unions, few students have offered hypotheses which explicitly attempt to account for the origin and/or persistence of such unions.

M. G. Smith (1962) has presented a wealth of statistical data in support of his hypothesis that specific mating patterns underlie the various forms of family organization in the Caribbean. He has demonstrated that the pattern of consensual mating underlies the matrifocal family in that area. However, he does not deal with the origin and persistence of the mating patterns themselves. Nevertheless, the data suggest that demographic and economic factors are important determinants of these patterns. For example, where the sex ratio is altered by the necessity that males migrate to find work, women often enter into extramarital unions with single or married men who remain behind. Such alliances may or may not entail co-residence.

Consensual unions may constitute a stage in the development of domestic groups and as such are not so much alternatives as preludes to marriage. In parts of the Caribbean where great prestige is attached to church marriages followed by festivities requiring the outlay of large sums of money, couples often assume the roles of husband and wife by mutual consent until such time as they can afford a religious marriage ceremony. Thus, many couples establish a common domicile and bear children before they enter into matrimony "before the eyes of man and of God."

This raises an important point. Even though, in most parts of the modern world, marriages may be contracted without religious ceremonies, historically marriage was the concern of religious institutions before it became the official concern of the state, and most religious doctrines still include prescriptions and proscriptions regarding marriage. Where the influence of religious tradition is particularly strong, civil marriages may be regarded as little more than alternatives to or complements of "true marriage." One of the consequences of this, as evidenced in parts of the Caribbean, is that couples enter into extramarital relationships until such time as they can finance the religious and convivial ceremonies as well as fulfill the legal requirements for marriage.

Marital stability and divorce

The ambiguities entailed in the concept of marital stability have been succinctly stated by David Schneider:

Stability may be defined in terms of the change of rules or expectations over time or in terms of the degree to which the rules or expectations are conformed to. Stable marriage may be defined as stable jural relations irrespective of conjugal relations, as stable conjugal and jural relations, or simply as stable conjugal relations. (1953, p. 56)

Thus, divorce, defined as the lawful dissolution of jural ties established at marriage, may occur relatively infrequently even though separation and other breaches in conjugal relations occur relatively frequently. In traditional Nuer society, the jural bonds established by marriage were stable; divorce, signified by the return of bridewealth, was rare. On the other hand, conjugal separation was relatively frequent. Max Gluckman (1950) was one of the first anthropologists to deal with the factors which contribute to the jural stability of marriage in preindustrial societies. His data on the Lozi and the Zulu led him to the hypothesis that the stability of jural relations established by marriage is correlated with the presence of patrilineages. He argued that where the "principle of father-right" prevailed, as among the Zulu, there was a complete and final transfer of women into their husbands' lineages (from which their children obtained their legal rights), and he suggested that this fact accounted for the virtual absence of divorce in such societies.

In a reconsideration of the Gluckman hypothesis, Fallers pointed out that not all patrilineal societies provide for the absorption of women into their husbands' lineages. He suggests that where women retain rights in their natal patrilineages, patriliney contributes to the jural *instability* of marriage by dividing the loyalties of spouses. Fallers (1957) found among the Busoga a relatively high incidence of divorce, which he attributed in part to the fact that loyalties to natal lineages undermined the bonds established at marriage.

Leach (1961a, pp. 114-123), Cohen (1961), and others have contributed to the discussions of marital stability begun by Gluckman, Schneider, and Fallers. However, there is yet to be undertaken the quantitative and comparative analyses required for a definitive statement on the determinants of stability in the jural aspects of marriage. Whether the aim is to isolate the determinants of differential rates of divorce within a single society or to account for the differences in the divorce rates

reported for various societies, care must be taken to insure that the data utilized are in fact representative of the populations discussed. Moreover, more attention must be given than has been in the past to the limits of the utility of numerical data, which, at best, can be considered reliable for relatively short time spans.

The separation of spouses is usually taken as an index of instability in conjugal relations. However, it should be obvious that separation can only be taken as indicative of the disintegration of conjugal bonds when the coresidence of spouses is a societal norm. Even in these cases, separation does not always signal instability in conjugal relations. Among the Yoruba, it is common to find women living and working in one place while their husbands live and work in another. So long as these women are not known to have committed adultery, and so long as they fulfill certain responsibilities to their husbands and their husbands' lineages, their conjugal relations are not necessarily impaired.

The distinction drawn by Schneider between stability in conjugal relations and stability in the jural aspects of marriage relations is useful in the analysis of marriage in contemporary societies. For example, it would be useful to make such a distinction in discussions of marriage patterns in the Caribbean and in the United States. As has been pointed out, among some of the lower-class populations in these areas, consensual mating is common. Not all the parties to consensual unions are persons who have never been legally married. In fact, where the economics of divorce are a deterrent to the lawful dissolution of marriage, consensual unions are often an alternative to divorce and remarriage. Hence, the jural relations established at marriage are often maintained even though conjugal relations are completely or partially severed.

Most of the societies whose marriage systems are described in the anthropological literature are now incorporated into independent states. The very existence of these states signals changes in the rules regarding the establishment of marital contracts, since all contemporary states reserve the right to define what types of union constitute legal marriage.

There is general agreement that the economic and demographic changes taking place in the "developing areas" are also effecting changes in traditional marriage systems. However, Goode (1963) has pointed out the difficulties involved in isolating cause-effect relationships between changes in a society's family patterns, including marriage, and

changes in its economic organization. Considerable refinement in research strategies is necessary before it will be possible to state with confidence the extent to which, the precise ways in which, and the specific points at which the spread of industrial technologies and the growth of cities impinge upon or serve to undermine traditional family structures and marriage patterns.

Some of the studies of marriage found in the anthropological literature provide convenient points of departure for investigations of changes in the rules and behavior associated with marriage in different parts of the world. However, it is obvious that analyses of changing patterns of marriage require the collection of a larger body of quantifiable data than is available in most existent anthropological studies of marriage. Whereas most of the marriage systems described in the anthropological literature lent themselves to representation in terms of mechanical models, such models are becoming increasingly inadequate as representations of particular systems and as bases for comparative studies. The rules governing the establishment of marriage contracts, the factors influencing the choice of spouses, the rights and obligations entailed in conjugal roles, and the behavior of persons in these roles are sufficiently variable in any one system to require partial or total representation by means of statistical models. With the construction of such models, we can begin the assessment of the directions and rates of change in marriage systems and the isolation of the specific variables which account for these changes.

MARRIAGE ALLIANCE

All societies prohibit marriage with certain relatives, but some societies complement this prohibition by prescribing, or preferring, marriage with other relatives. In this way two kinds of cousins are sometimes distinguished, marriage being prohibited between those who are children of siblings of the same sex ("parallel cousins"), while it is prescribed between children of siblings of opposite sex ("cross-cousins"). This disposition is generally accompanied by exogamy. This article attempts to sum up recent developments in the theory of cross-cousin marriage.

Descent and alliance

The expression "marriage alliance," in which "alliance" refers to the repetition of intermarriage between larger or smaller groups, denotes what amounts to a special theory of kinship, a theory developed to deal with those types of kinship systems that embody positive marriage rules, though it also affords certain general theoretical insights regarding kinship. Two points may be noted at the outset: (1) The combination of the positive marriage rule with exogamy, or at the very least with a prohibition against marriage between parallel cousins, is essential to the type of system under description here; a preference for marriage with

the father's brother's daughter, as found among some Islamic peoples, is a quite different phenomenon. (2) The approach here presented is essentially common to several writers, though an element of personal interpretation is inevitable.

In the initial stages of kinship studies, the reconstruction of fanciful marriage rules (or mating arrangements) as having supposedly existed in the past was widely used in order to explain seemingly strange ways of classifying relatives (kinship terminologies). This practice has brought discredit, in the eyes of some, to the study of both marriage rules and terminologies. In 1871 Lewis Henry Morgan made two assumptions: (1) terminology reflects behavior, and hence, (2) if a terminology cannot be understood from present behavior, it must be because the behavior it reflects belongs to the past. [*See the biography of MORGAN, LEWIS HENRY.*]

Quite apart from the difficulty of reconstructing past behavior, anthropological thought in this matter is still ethnocentric. The underlying assumption is that all peoples entertain the same *ideas* about kinship; their classifying of relatives in different ways is, therefore, due to differences in *behavior*. Fully excusable in Morgan, such an assumption is less so today.

W. H. R. Rivers recognized the link between an actual marriage rule (symmetrical cross-cousin marriage) and a certain type of terminology (often called "bifurcate merging"). For Rivers, the marriage rule was the cause, the terminology the effect, and he saw his task as explaining the marriage rule itself. [*See the biography of RIVERS.*] Once again, terminology reflects behavior, and again historical speculation is called in, this time to discover the "origin" of one item, which is in fact essentially a normative trait. In our time the different features of a kinship system are, in practice, often considered in isolation or are hierarchized according to what is assumed to be their degree of reality or determinativeness. This tendency, if not found in such crudity as in the past, still exerts considerable pressure even on the best minds, and that it constitutes a major obstacle to the understanding of certain kinship systems can be shown by the example of Australian kinship, a classical subject for kinship theory. In Australian section systems, descent is overstressed; the reasons that may elsewhere justify this emphasis are here misplaced, for it prejudices the consideration of other elements in the system.

In writing about Australian kinship systems, authors vie with each other in stressing that in

Figure 1

symmetrical cross-cousin marriage arrangements, double descent is always present or implied. This is unobjectionable in itself, but in the literature it is accompanied by a bias which makes itself obvious by repetition, whether it be in B. Z. Seligman's attempt to reduce the "type of marriage" to "forms of descent" (1928, p. 534), however strange the latter forms may appear, or in Radcliffe-Brown's overemphasis upon descent, or in Murdock's outbidding of Radcliffe-Brown in this respect. Radcliffe-Brown was not content with finding an underlying matrilineal exogamy in his classic Australian patrilineal systems and with seeing in what is now called "double descent" a widespread principle of Australian kinship. He claimed that his second kind of exogamous group actually "existed," whereas he had only inferred it (1931, pp. 39, 439); the point is insisted upon by Goody (1961, pp. 6 ff.). It is perplexing later on to find Murdock opposing Radcliffe-Brown, while praising the same discovery in others; but the crux of the matter is that in Murdock's opinion Radcliffe-Brown had not gone far enough in stressing descent and descent groups, for Radcliffe-Brown had maintained, at another level, the primacy of individual relationships and marriage rules over the arrangement of groups (Murdock 1949, pp. 51 ff.).

Actually, the hypothesis of underlying matrilineal exogamy among the Kariëra and Aranda accounts for the allocation of alternate generations to different groups. Among them, the patrilineal group is conceived not as a unity over a continuous series of generations but as a duality made up of two alternate generation-sections, called by different names and following different marriage rules (the grandson falling back, so to speak, into the grand-

father's section). This is the simple, concrete sociological fact, widespread in Australia. If we take this for granted, together with intermarriage between the named sections, we can in each case draw a simple diagram of the whole tribe. In Figure 1 the sign [=] denotes intermarriage in both directions, the letters A, B, etc., represent patrilineal groups, and the numbers 1 and 2 are used for the two alternating generation-sections in each patrilineal group. The system of Ambrym (Balap) is easily represented in the same fashion (Deacon 1927). All three systems represent variations on the same theme, the number of patrilineal groups being respectively two, four, and three, the number of sections four, eight, and six. Each of the three systems may be conceptualized as forming a single whole through a regular chain of intermarriage and patrilineal descent. The differences in the arrangement follow necessarily from the numbers of groups (for details, see Dumont 1966). I do not pretend that a second unilineal principle cannot be said to underlie these systems, but only that the above is a simpler view of them. Let us now turn to the general theory that, like the above analysis, recognizes intermarriage as a basic element in those systems which possess a preferential or prescriptive marriage rule.

Lévi-Strauss

We must neglect the scholars who had previously advanced the distinction and description of the types of cross-cousin marriage (e.g. Fortune 1933; Wouden 1935) and start with the general theory of Lévi-Strauss. His monumental book *Les structures élémentaires de la parenté* (1949) goes far beyond our limits. Josselin de Jong (1952) has

provided an able summary of the book, while Leach (1961) and Needham (1960) have sympathetically, but sharply, criticized its detail. Our concern here is only with its leading ideas.

From the present point of view, the work is first of all a comparative study of positive marriage rules, informed by a general theory of kinship. Preferential marriage rules and marriage prohibitions are accounted for within an integrated body of theory. The prohibition of incest is recognized as universal; it is seen as a basic condition of social life. A man cannot take in marriage the women who are his immediate kin; on the contrary, he has to abandon them as wives to others and to receive from others his wife or wives. Lévi-Strauss considers this situation as a universal principle which lies beyond sociological explanation—and which implies an opposition between consanguinity and affinity as the cornerstone of kinship systems. He views marriage as predominantly a process of exchange (between one man and other men or between one domestic group and others), and he sees in positive marriage rules devices through which this exchange is directly regulated, giving rise to what he has called "elementary" structures.

Let us note that a kinship system is viewed here, starting from its basis in the incest prohibition, as an entirety resting on an opposition and not as a mere collection of features in which one feature might, for a priori reasons, be considered to determine the others. Abstractly, a kinship system is taken as combining a number of features (descent, inheritance, residence, affinity), and an effort is made to characterize the whole by the relations that prevail between the different features. Thus, a system is called harmonic if all transmission between generations takes place in one and the same line, dysharmonic if some features are transmitted patrilineally, others matrilineally. The rule of cross-cousin marriage, where it exists, correlates with this. Theoretically three types may be distinguished: bilateral, matrilinear, and patrilinear. In bilateral cross-cousin marriage, the spouse is at the same time mother's brother's child and father's sister's child. Two intermarrying groups exchange women as wives and thus constitute a self-sufficient unit. Lévi-Strauss has called this form "closed" or "restricted" exchange (*échange restreint*) and correlated it with dysharmonic transmission. In opposition to this type, he has stressed the quite different properties and implications of matrilinear cross-cousin marriage. This type had been less clearly recognized by previous writers, though he does not consider the Dutch literature on Indonesia in which the type had been characterized (e.g. Fischer 1935;

1936; Wouden 1935). In this type, a man marries his mother's brother's daughter; a given line B takes wives from a line A and gives wives to a line C, generation after generation. Intermarriage is thus asymmetrical, and if the society is conceived as a number of discrete groups giving and receiving women in marriage, the simplest system is that of a circle: at the end of the series, Z receives from Y and gives to A (called the "circulating connubium" by the Dutch scholars). This is what Lévi-Strauss calls "generalized exchange." In opposition to the closed type, it requires at least three groups and may accommodate any number of groups. This type correlates with harmonic transmission, which may be either matrilinear or patrilinear. Here the identity of the intermarrying group emerges from the network of relationships, for one group is not closely dependent on any other single group, nor are two successive generations distinguished. Relatives belonging to different generations within the same group of affines are terminologically equated. Since intermarriage is directionally oriented—a group does not receive wives from the group to which it gives its daughters—there is a probability of difference of status between wife-givers and wife-takers. For a discussion of the further consequences, see Leach (1961, chapter 3; cf. Fischer 1935).

The third type, the patrilinear, is only cursorily treated in Lévi-Strauss's treatise; it appears there as a kind of abortive crossbreed between the first two types and is omitted here because it is somewhat controversial (Needham 1958b; Lane 1962).

Some of the objections that have been leveled at Lévi-Strauss's theory can be briefly mentioned. One, forestalled by Lévi-Strauss, is that he argues exclusively about viripotestal societies; another is that his idea of marriage is naive, although this is beside the point, since he was actually concerned solely with the forms and implications of intergroup marriage. A more radical criticism can be directed at the fundamental character and explanatory value of "exchange" in Lévi-Strauss's scheme (discussed in Wolfram 1956). To view the prohibition of incest as the basis for the opposition between consanguinity and affinity appears tautological to those who think of consanguinity itself as fundamental and self-explanatory or appears insufficient to those who would like a psychological explanation. Viewing marriage as an exchange may be questioned on two counts. First, it introduces an arbitrary analogy between women and chattels, women being supposed, for instance, to be universally the most prized of "valuables." Second, "exchange" here tends to be given so wide and inde-

terminate a meaning as to be practically devoid of content. While this is true of "indirect exchange" and even more so of "reciprocity," the notion of exchange is certainly useful within limits. In still another critique of Lévi-Strauss, Homans and Schneider (1955) argue, in the last analysis, that to look at kinship systems as wholes having explanatory value in relation to their parts is to resort to "final causes." This critique has itself been carefully refuted by Needham (1962).

Developments

Since 1949 the Lévi-Straussian theory has been tested and has undergone partial modifications and developments. To mention only the major themes, we have first the clear-cut distinction, advocated by Needham, between prescription and preference in marriage rules. He claims that prescription alone has "structural entailments" in the total social system, and that Lévi-Strauss has dealt only with prescription or at any rate should have done so (Needham 1962). "Prescription" is here defined more as the characteristic of a system than as simply a marriage rule: it involves the combination of a rule prescribing some relatives and prohibiting others, a corresponding terminological distinction, and a sufficient degree of observation of the rule in practice (Needham 1958a, p. 75; 1958b, p. 212). The advisability of the distinction has been challenged by R. B. Lane (1962, p. 497). At first sight the distinction seems justified, and there is no objection to isolating a clear-cut type of "prescriptive alliance." That there is a danger of underestimating the importance of other types is apparent from the exacting criteria by which the author excludes the recognition of forms of patrilineal intermarriage as "prescriptive" in his sense (Needham 1958b). These latter forms, like preferential marriage in general, do have "structural entailments" of a kind, as we shall see. Moreover, the two forms are not easily distinguishable; the distinction, so presented, is more one of levels than of systems (for a recent clarification of this question, see Maybury-Lewis 1965).

The main development has probably been a refinement of the concept of alliance and the substitution of a more structural for a more empirical notion. At the start the theory, although anchored in the notion of complementarity, was in large part concerned with the exchange or circulation of women between the major exogamous components of the society. To begin with, three authors have asserted that the units which may be said to exchange women are, in concrete cases, smaller than

the exogamous units. In 1951 Leach sternly insisted—with empirical, if somewhat dogmatic, good sense—that the agents arranging marriages are as a rule the males of the local descent groups, as distinct from the wider exogamous units and from the "descent lines" used in terminological diagrams and often unwittingly reified by the analyst into actual groups (see Leach 1961, p. 56; cf. Needham 1958a). Quite logically, Leach went on to criticize the assumption that a matrilineal marriage rule should necessarily result in the groups intermarrying "in a circle," an idea which Needham, on the other hand, tried to refine (1958a; 1962). A criticism from Berting and Philipsen may also be noted: to be meaningful, they suggest, the "marriage cycles" must be limited in number, and the people themselves must be aware of them (Needham 1961, p. 98). While such "alliance cycles" (Needham) do meaningfully exist in some cases, their existence does not exhaust the function or meaning of marriage alliance. On this all our authors agree, for Lévi-Strauss (1962, p. 333) himself recently recognized—if my interpretation is correct—that "conscious rules" have emerged from recent research as more important than their results in terms of "exchange." Leach had pointed out that, in the absence of cycles, the basic relationship is "one of the many possible types of continuing relationship between paired local descent groups" (1961, p. 101). Elsewhere, while marriage alliance does not result in a system of exchange at the level of the group as a whole, it is an integral part of the system of categories and roles as conceived by the people studied (Dumont 1957, pp. 22, 34).

Needham has gone furthest in submitting Lévi-Straussian structuralism to criticism from the inside and in referring the "mediating" concepts of exchange and reciprocity back to that of (distinctive) opposition (1960, p. 103). The more fundamental "integration" is not that of groups but rather that of the categories as it occurs within the social mind: the marriage rule is part and parcel of this system of ideas. Like everything else, social relationships are defined by classification. Studying the "symbolic order" of the Purum and others, Needham (1958a) found that asymmetrical intermarriage, although it could not function with less than three intermarrying or "alliance groups," can be dualistically conceptualized (wife-givers and wife-takers) in accordance with an over-all dualist scheme. Here are found "structural entailments" different from the group arrangements on which attention had first focused. The expression "mar-

riage alliance" thus covers both the general phenomenon of mental integration and the particular phenomenon of group integration.

In its restricted field this truly structural theory alone transcends the bias inherent in our own culture. Such expressions as "cross-cousin marriage" are technically useful but basically misleading. Real understanding is reached when the marriage rule understood as marriage alliance is seen as giving affinity the diachronic dimension that we tend to associate only with descent and/or consanguinity. By this means we are able to transcend the limitations of thinking based upon our own society and make comparisons in terms of the basic concepts involved (consanguinity and affinity).

Much remains to be done. Certainly the implications of marriage alliance for status, economy, and political organization (i.e., the physiology of the system) should be worked out (Leach 1961, chapter 3). But even regarding the morphology, our analyses are as yet imperfectly structural; we still take too much for granted in the study of terminologies. Before attempting ambitious (re)constructions, the basis in comparative data must be strengthened and extended, and we must obtain a clearer view of the limits of the logical integration of features, or conversely, of the plasticity and tolerance of systems, which can in some cases go so far as to deny in effect the ideological primacy postulated above in principle.

MARSH, GEORGE PERKINS

George Perkins Marsh (1801-1882), an American geographer, is known today primarily as the founding father of the conservation movement. His contemporaries regarded him as the most comprehensive American scholar of the time. His enduring contributions to knowledge stemmed from an unusual combination of historical and ecological insights. As a social historian, Marsh broke new ground in treating the story of mankind as the history of the use and misuse of resources.

As an ecologist, he saw the history of nature mingled with that of man and traced the motives, the techniques, and the consequences of man's impact on the earth. Although he was not a trained naturalist, Marsh manifested an extraordinary awareness of the fragile interdependence of all aspects of nature, physical and biological, and of their multiform significance for mankind.

The scion of a patrician family in frontier Vermont, Marsh graduated from Dartmouth College and practiced law in Burlington, meanwhile engaging in business—farming, lumbering, woolen manufacturing, railroad development, marble quarrying—and in politics. He served in the state legislature and for six years in Congress. As a reward for services to the Whig and Republican parties, he was appointed United States minister to Turkey from 1849 to 1853 and to Italy from 1861 to 1882, the latter an unequaled tenure of office. This diplomatic career gave him an opportunity to travel widely and made possible the leisure essential for his scholarly work.

Marsh's first contributions were in linguistics. Attracted by new developments in the study of Teutonic languages, folklore, and cultural origins, he edited the first Icelandic grammar in English, delved into the history and literature of Old Norse and related tongues, and became the American promoter for C. C. Rafn's monumental *Antiquitates americanæ*, a collection of Icelandic sagas bearing on the Iceland-Greenland-Vinland settlements. Marsh's historical studies of the English language were the standard texts during the 1860s, and he was in continual demand as editor, adviser, and critic of dictionaries, including the *New English Dictionary*. Familiarity with an extraordinary range of source materials in twenty languages made Marsh a first-rate, if not profoundly original, etymologist.

His work as a scientific middleman was of more lasting significance. In the House of Representatives, Marsh helped to create, to staff, and to shape the Smithsonian Institution, guiding its early ventures in archeology and in natural science and guarding its research endowment against congressional incursions. He himself added animal specimens from Turkey, Egypt, and Palestine to the Smithsonian collections. On his return from Turkey he strongly urged the introduction of camels as beasts of burden in the American West—an enterprise initially successful but aborted by the Civil War.

A utilitarian zeal directed and inspired Marsh's best work. As early as the 1840s he publicly advocated measures of physical improvement and

conservation: the establishment of nurseries for forestry research and the regulation of logging to prevent excessive and flashy runoff and consequent flooding and desiccation. Not until he returned to Italy in 1861, however, did Marsh bring together the materials he had long been collecting into a systematic analysis of man's manipulation of the natural environment. Published in 1864, *Man and Nature* showed how man differs from nature, how nature operates within itself, and what happens to woods and waters, mountains and deserts, when men clear, farm, dam, and build.

In surveying man's impact, conscious and unconscious, Marsh did not overlook the improvements but stressed the accompanying and resulting damage. Technology had enabled man to derange natural balances and might ultimately, Marsh feared, reduce the surface of the earth "to such a condition of impoverished productiveness, of shattered surface, of climatic excess, as to threaten the depravation, barbarism, and perhaps even extinction of the species" ([1864] 1965, p. 44). *Man and Nature* was the first book to controvert the American myth of an inexhaustible earth. Its immediate impact was more moral than practical, but by 1907, when it had gone through three editions, the basic principles of *Man and Nature* were embodied in the national conservation program.

In geography, Marsh is also important as an early and effective critic of environmental determinism, then popularized in the works of Arnold Guyot. How could man be viewed as the product of environment, when man himself had the power to alter that environment—and had in fact done so over most of the earth's surface? The mistakes man had made through ignorance or greed could, Marsh thought, in most cases be rectified by applying scientific principles of land management, by avoiding waste, and by public control of resources.

MARSHALL, ALFRED

Alfred Marshall (1842–1924) is one of the great names in the development of contemporary economic thought, and the book by which he is most widely known—*Principles of Economics*—is one of the high points in the literature of social science. His influence was enormous; so much so that the first 25 years of twentieth-century economics may be described as the “age of Marshall” and subsequent developments as extensions of and counter-movements to his influence. Moreover, even when due allowance is made for the natural progress of economic science since Marshall’s time, it is remarkable how much of the Marshallian framework remains. These well-known points require restatement because the positive effects of the Marshallian influence are questioned today as perhaps never before. One could agree with criticisms if they were merely objections to the view sometimes expressed that “it’s all in Marshall,” meaning that little or no progress has been made in economics since he wrote. It would indeed be deplorable if scientific ideas worked out almost one hundred years ago were still the last word. (An analogy with the positions of Marx and Freud is appropriate here.) However, much of the contemporary criticism goes deeper than this; it argues that the Marshallian tradition checked the development of economics by diverting attention from real issues (by which is primarily meant macrotheory) much as Ricardo was alleged to have done in an earlier generation. The merit of these criticisms will be examined carefully later in this article.

Alfred Marshall was born in Clapham—then a leafy London suburb—in 1842. His father, John Marshall, held the respectable middle-class position of cashier in the Bank of England, and the family lived in modest comfort. Marshall’s father was of a rather severe, evangelical frame of mind, almost a textbook example of what is loosely called Victorianism, and closely supervised his son’s education. This paternal control and repression had a marked and lasting effect on Marshall; his

pronounced tendency toward hypochondria, his unwillingness to commit himself unequivocally in print without massive documented qualification, his fear of indolence and idleness, and his ultimate rejection of “pure pleasure” activities (such as mathematics) have their roots in the experiences of his early years. His education was planned as basically a preparation for ordination in the Anglican church. He was expected to go up to Oxford with a classics scholarship, which would lead to a fellowship and a church living. However, he rejected this plan—rebellng not against orthodox theology but against further study of the classics—and with funds borrowed from an uncle proceeded to St. John’s, Cambridge, where he read mathematics. Marshall was one of the best mathematics students of his generation in England (in 1865 he was second wrangler in the tripos examination). This is an important point to bear in mind in evaluating his ambivalent attitude toward the use of mathematical methods in economics—in any event, his criticisms were not based on ignorance. Marshall came into economics with much more mathematics training than did Jevons or Walras.

After graduation Marshall was elected to a fellowship in mathematics and gradually came under the influence of a group of philosopher-dons who were increasingly concerned with the social problems of industrial England. Marshall’s interests centered initially on philosophy and ethics, which were then still at the frontier of social science, but worry about social conditions and the realization that poverty was at the root of many social evils led him into economics. Indeed, to Marshall the problem of poverty was not only central to the study of economics but its ultimate rationale. As he later wrote in the *Principles*, “the study of the causes of poverty is the study of the causes of the degradation of a large part of mankind” ([1890] 1961, vol. 1, p. 3).

In 1877 he married Mary Paley, a former student of his and one of the first women to be educated at Cambridge. Upon his marriage he was forced to resign his fellowship. He was for a short while principal and professor of political economy at the then University College of Bristol, became a fellow at Balliol in 1883 (after the requirement of celibacy had been eliminated), and the following year returned to Cambridge, to the chair of political economy vacated by Henry Fawcett; there he reigned until his retirement in 1908, when he was succeeded by his star pupil, A. C. Pigou.

Marshall’s published output was not large, especially considering that he was active almost until the time of his death. Several books—*The Pure*

Theory of Foreign Trade and The Pure Theory of Domestic Values (1879a), *Principles of Economics* (1890), *Industry and Trade* (1919), *Money, Credit & Commerce* (1923), and *The Economics of Industry* (1879b), written jointly with Mary Marshall (which he tried to have withdrawn for complex personal reasons not bearing on its merit), a handful of articles, mainly reprinted in the *Memorials of Alfred Marshall* (1925), edited by Pigou; and a series of official memoranda and evidence before royal commissions (contained in *Official Papers*, a volume published in 1926) make up his total written contribution.

Marshall's reluctance to commit himself to print—the *Principles* did not appear until he was 48—makes it difficult to assess his originality. Ideas first published in the 1890s, such as Marshall's statement of the theory of marginal utility, had been worked out and presented orally by him in the late 1860s, i.e., before the publication of the theory in the works of Jevons, Walras, and Menger. As J. M. Keynes put it in his famous obituary of Marshall, "The task of expounding the development of Marshall's economics is rendered difficult by the long intervals of time which generally separated the initial discovery and its oral communication to pupils from the final publication in a book to the world outside" (1924, p. 322).

Intellectual background. Efforts to disentangle the various influences on Marshall's thinking as an economist are made difficult by his modesty—his desire to emphasize the continuity of thought—and also by his rather confused accounts of these influences. Marshall's first reading in economics was Ricardo and Mill; he described his early efforts as attempts to translate the ideas of these writers into differential equations. The most important single influence was surely Mill's *Principles of Political Economy* (1848), and a good way to get perspective on Marshall's contribution is to compare the two *Principles*. Also, what little mathematical economics then existed was open to Marshall, although it was not to most of his contemporaries. He clearly learned a lot from Cournot—especially about the use of continuous functions in economics. Thünen's *Der isolierte Staat* (1826–1863), with its hints of marginal productivity analysis, was also influential. German (Hegelian) philosophy and the historical school of economists are commonly mentioned as influencing him (Marshall studied in Germany for a year). However, it is difficult to see concrete evidence of these systems of thought in his work. There is no dialectic and no historicism, although in his concern with empirical investigation he was closer to the histor-

ical school than to the English classical school. His emphasis on the continuity of growth and his perpetual references to biology suggest the influence of social Darwinism—acquired through Herbert Spencer.

Methods

Much of the discussion of Marshallian economics deals with his methods of analysis. These methods are not particular hypotheses or models proposed by Marshall but, rather, represent ways of setting up a problem or partitioning it so that it can be solved. The central Marshallian method is usually termed "partial analysis" or "partial equilibrium analysis" and is often loosely referred to as the *ceteris paribus* approach. The Marshallian partial equilibrium approach is frequently contrasted with the method of general equilibrium associated with Léon Walras, and the contrast is usually considered unfavorable to Marshall. Indeed, this approach is sometimes regarded as one of the major weaknesses Marshall bequeathed to economic science. Since the question of partial versus general equilibrium has loomed so large in the literature, some discussion of the central issues is imperative. As Marshall realized, the general equilibrium approach is not *de facto* a fruitful approach to such practical problems as measuring the effect of an import duty on the price of a commodity or the effect of a fall in the final product price on the demand for a particular grade of labor. It is not very helpful to be told that "everything depends on everything else" and that a change in one parameter will have effects throughout an economic system. Partial analysis is a method by which an economy is partitioned so that the main effects of a parameter shift in a particular micromarket can be highlighted without considering the spillover into other markets; hence, this method also ignores the feedback effects from the spillover. There are, of course, obvious dangers inherent in this method, but the answer lies, not in the general equilibrium approach, but in better specification of the partial model. [See ECONOMIC EQUILIBRIUM and the biography of WALRAS.]

Let us take a specific example to illustrate the use of the *ceteris paribus* approach of partial equilibrium analysis and the related concept of comparative statics. We can draw up a demand schedule for a commodity and show the amount demanded per unit of time as a decreasing function of the price of the good. The relationship is *ceteris paribus*, i.e., it assumes that other factors influencing demand—such as the price of substitutes—are given, as are factors such as incomes, tastes, and expect-

tations. In a free market, if an equilibrium exists it will be where supply equals demand. If one of the *ceteris paribus* conditions is relaxed, the demand curve shifts, and the new partial equilibrium solution is then considered. This leads to the comparison of the two sets of equilibrium values of the variables under discussion. The method of comparing equilibrium solutions is called comparative statics because it does not permit the tracing of the time paths (between the two points of equilibrium) of the variables involved. [See STATICS AND DYNAMICS IN ECONOMICS.]

Marshall's ultimate objective was to develop a full-fledged theory of dynamic change and growth. In the preface to his *Principles* he wrote, "The main concern of economics is . . . with human beings who are impelled, for good and evil, to change and progress. Fragmentary statical hypotheses are used as temporary auxiliaries to dynamical—or rather biological—conceptions; but the central idea of economics, even when its Foundations alone are under discussion, must be that of living force and movement" ([1890] 1961, vol. 1, p. xv). The immediate objective of Marshall's formal analysis was more limited: namely, the comparison of static equilibrium positions. Yet, even within this restrictive framework he was able, by his use of the time-period concept, to approximate dynamic analysis. His approach was to divide the adjustment, say, of price to changing demand or supply conditions into a series of adjustment periods. These periods should be regarded as measured by operational, not clock, time—the market period for one sector or industry may be (in terms of clock time) a longer one than the market period for another industry. The important consideration is which *ceteris paribus* assumptions are relaxed in successive periods.

Marshall's time division is as follows: the market period, the short period, and the long period. The market period takes the production of the commodity in question as fixed, so that supply can vary only if sellers have a reserve price for their own product. The condition for equilibrium (for all time periods) is that the market be cleared, i.e., that demand equal supply. Short-run equilibrium considers supply to be partially adaptable, in the sense that increased production can occur but capital equipment and certain other overhead items are held constant. In modern economics, analysis of this short period with partial adaptation is equivalent to an analysis of the law of variable proportions, although it is not certain that Marshall himself was precisely clear about the distinction between variable proportions and returns to scale. The Marshallian long period allows for optimal capital stock adjustment. The

market is cleared within a framework in which supply can be considered to be fully adaptable because all factors (excluding entrepreneurship) have been adjusted to the situation. It was by means of this differential adjustment of supply that Marshall restated, within the supply and demand framework, his theory of value. The classical emphasis on costs is now seen as a particular hypothesis: that in long-run adjustment there are constant returns to scale.

Figure 1 illustrates this. SS is the fixed-stock supply curve (on the assumption of zero reserve price); $S'S'$ the short-run supply curve and $S''P$ the long-run supply curve. With demand at DD , the long-run price is OP . Now let demand rise to $D'D'$. Then long-run equilibrium price will again be OP , but price will pass through the stages OP'' and OP' , and quantity will increase. [See DEMAND AND SUPPLY.]

Figure 1

Marshall also hinted at the analysis of a fourth time period, in which factor supplies are allowed to adjust to changes in their underlying determinants. In the absence of innovation, in this period the economy reaches the full equilibrium solution for a stationary state.

Marshall was cautious and basically skeptical about the use of mathematics and theoretical statistics in economics; for better or worse, he did not foresee the mushrooming of mathematical economics and econometrics. The Marshallian attitude—which became embodied in the Cambridge tradition and especially in the work of Pigou and Keynes—is seen in the *Principles*, where the mathematical statements are in footnotes and in a mathematical appendix. The grounds for minimizing the formal use of mathematics in the final presentation (although not in preparation) were twofold: first, the need to communicate; and second—and much more important—the fear that sets of equations necessarily omit or distort many relevant influences

and considerations. Marshall set out the matter squarely in a letter to A. L. Bowley dated February 27, 1906:

[A] good mathematical theorem dealing with economic hypotheses was very unlikely to be good economics: and I went more and more on the rules— (1) Use mathematics as a shorthand language, rather than as an engine of inquiry. (2) Keep to them till you have done. (3) Translate into English. (4) Then illustrate by examples that are important in real life. (5) Burn the mathematics. (6) If you can't succeed in 4 burn 3. This last I did often. ([1925] 1956, p. 427)

Marshall had grave doubts as to the reasonableness of the assumptions underpinning the then existing techniques of theoretical statistics (which meant, basically, regression analysis) when applied to social science data. He had no doubts, however, about the need to be steeped in the empirical facts of any situation under analysis. He always emphasized deep statistical and historical knowledge of the area being investigated and referred again and again to the complexity of economic problems and the naïveté of simple hypotheses. Like Adam Smith, Marshall had a profound knowledge of the workings of economic systems. When asked, for example, by the Gold and Silver Commission of 1887/1888, "Do you speak with knowledge . . . of the working classes?" he replied (somewhat pompously but with all honesty), "I speak from personal observation ranging over many years, and a study of almost everything of importance that has been written on the subject" (*Official Papers*, p. 99).

Marshall's oft-quoted definition of economics—"the study of man in the ordinary business of life"—was not an attempt to demarcate the discipline precisely from other social sciences. Marshall's basic view on the scope of economics is best expressed in the sentence "The less we trouble ourselves with scholastic inquiries as to whether a certain observation comes within the scope of economics, the better" ([1890] 1961, vol. 1, p. 27). He used the term "ordinary business of life" to emphasize the point that economics is not the study of the workings of a fictional economy populated by abstract economic men: it is concerned with the real world around us.

Contributions to theory

Marshall's central theoretical contribution was the working out of the rigorous economics of the stationary state. For Marshall this was not, of course, the ultimate end of economics—it was indeed but the preface. To point the way to the conclusion—the working out of a full-fledged growth

model—Marshall interlarded his stationary-state framework with bits and pieces of the dynamic process. It is this mixture that makes Marshall's *Principles* such difficult reading for some.

Theory of demand. Marshall developed utility theory for two reasons: first, to place restrictions on demand functions; and second, to create what he hoped would be powerful tools of welfare economics. The Marshallian demand curve relates the demand for a commodity per unit of time to its own price. The relationship is *ceteris paribus*; in particular, other prices and incomes are assumed constant. There are certain ambiguities in this statement of inclusions within *ceteris paribus*, but for the moment these are set aside. Marshall's generalized "law of demand" states that the price of a good and the quantity demanded are inversely related. This restriction on demand functions is derived a priori from the form of the utility function that he postulated, which is laid out most clearly in the mathematical appendix to the *Principles*. He used an additive, cardinal utility function; this means that one may think of utility as being a measurable quantity (although in practice Marshall spoke of it as being only indirectly measurable, at the margin, by price) and also that the total utility that a consumer derives from his consumption of goods and services is the sum of the individual utilities derived from the consumption of each item in his budget. Symbolically, we have

$$U = \sum_i U_i,$$

where U_i is the utility derived from the consumption of the i th commodity and U is total utility.

The basic restriction given by the additive nature of the function is that interrelationships between goods are excluded (all cross-partial derivatives are zero). Further, the law of diminishing marginal utility operates with respect to each good; this means that extra units consumed of a given commodity will increase total utility at a decreasing rate. Thus, the addition to total utility induced by the n th unit of a commodity will be less than the increase in utility induced by the $(n - 1)$ st unit. In terms of the function above,

$$MU_i = \frac{dU}{dX_i} > 0; \quad \frac{d^2U}{dX_i^2} < 0.$$

It is assumed that the consumer seeks to maximize utility, given incomes and prices. The principle of substitution comes into full play here. By substituting at the margin, a consumer reaches his maximum utility point. Maximizing the utility function, subject to the budget constraint (i.e., that the quan-

ties of all goods and services purchased multiplied by their respective prices equals total income), yields the well-known Marshallian first-order conditions for a maximum. These can be stated in the following equivalent terms:

- (1) $\frac{MU_i}{MU_j} = \frac{P_i}{P_j}$, for all i and j ,
- (2) $\frac{MU_i}{P_i} = \frac{MU_j}{P_j} = \dots = \lambda$,
- (3) $MU_i = P_i \lambda$, for all i .

Here P_i represents the price of commodity i , and the constant term λ represents the marginal utility of income. A fall in the price of commodity i must lead to more of the commodity's being bought; this must be so to keep the equalities listed in eqs. (1) to (3). That formulation (as Marshall realized) avoids the implications of the income effects of a price change—this is the purpose of assuming constant marginal utility of income. [See UTILITY.]

Rigorously applied, the Marshallian assumptions appear to restrict elasticities of demand to unity, but it is clear from the body of the *Principles* that Marshall did not contemplate this restriction.

Strictly speaking, a *ceteris paribus* demand curve requires that real income be held constant as price changes, so as to eliminate from the analysis the income effect of the price change. Holding money income constant is insufficient, since the real value of money income is its command over commodities and if commodity prices change, this changes also. Marshall solved this problem intuitively, by talking in terms of money income but postulating small changes in the prices of commodities that make up a small portion of the consumer's budget, so that the error involved in using money income is "of the second order of small quantities" ([1890] 1961, vol. 1, p. 132). Milton Friedman has since put the demand curve on a more satisfactory analytic footing.

But for Marshall the object of demand theory was not just to place testable restrictions on demand functions; he also regarded the demand curve and the allied concept of consumer surplus as powerful tools of welfare economics. We shall consider this aspect after we have looked at Marshall's contribution to production theory and the theory of the firm.

Theory of production. Marshall spoke in terms of "real costs" when considering costs of production. By "real" he meant ultimately the disutility of both the labor and the waiting involved in producing and bringing a commodity to market. The emphasis on real cost seems to contrast with the Austrian notion of opportunity cost, but in fact it

is easy to reconcile the two concepts. In any case, in spite of Marshall's emphasis, he rather too easily assumed the equality of real and money costs and proceeded with his analysis in terms of the latter. Central to his theory of cost and production is the principle of substitution, which works here the same way it does in his consumer theory. The entrepreneur substitutes at the margin until the total cost of a given output is at a minimum or, what is the same thing, until the output from a given set of inputs is maximized. [See COST.]

Marshall was confused about the so-called laws of production and especially about the distinction between what has come to be called "variable proportions" and returns to scale; so, of course, was the whole profession until Viner's classic article of 1931. Marshall tended to compare decreasing returns with increasing returns, as though they were similar. Although he postulated that diminishing returns were historically connected with agriculture and with a situation in which the labor-capital input had grown relative to (fixed) land, he did not see the logical connection between the principle of substitution and the law of variable proportions. Increasing returns, looked at in an analytic manner, occur where increase in output is proportionately greater than the simultaneous increase of all inputs. In the course of his discussion of increasing returns, Marshall made the crucial distinction between internal and external economies, from which the whole notion of externality started. Internal economies are "those dependent on the resources of the individual houses of business" in an industry, while external economies are "dependent on the general development of the industry." Internal economies, where present, produce a falling long-run marginal cost curve for a firm, and hence threaten the stability of competition. Marshall realized this, and his "life cycle" theory of entrepreneurship was meant as a partial explanation of the survival of competition. External economies, on the other hand, are compatible with competition but raise serious welfare problems. [See EXTERNAL ECONOMIES AND DISECONOMIES.]

Central to Marshall's discussion of the theory of the firm is the concept of the representative firm—a notion which is not only tenuous and vague but apparently unnecessary for Marshall's own purposes, as critics like Lionel Robbins were quick to point out. Marshall's definition of the representative firm gets us nowhere; it is only by specifying the problem with which he was trying to cope that we see the purpose of the concept.

Two questions in particular worried Marshall. First, in the real world, firms clearly are capable of

expanding at falling marginal cost, yet industries do not become monopolized. Marshall's answer lies partially in the representative firm. The second, a closely related problem, concerns the estimate of the supply price of a product where industry output is taken as a given but the group of firms making up the industry are in a life cycle of birth, growth, decay, and death. According to Marshall's theory, the entrepreneurial life cycle prevents the continuing expansion of any *one* firm—an idea more appropriate to the days of small business than to those of the large corporation, where management is not dynastic. But apart from Marshall's exercise in social evolution, we still have the interesting problem, with disequilibrium at the firm level, of estimating supply price and, more generally, the industry supply curve. In contemporary economics the static solution to these problems, under perfect competition, is to sum the firms' marginal cost curves to obtain the industry supply curve. This supply price is equal to any firm's marginal cost; for Marshall, however, with his continual search for the dynamic solution, this answer was inadequate. A firm picked at random would not necessarily be typical in the sense that its costs would correctly reflect the sustainable degree of efficiency and level of economies for its aggregate output. It might be a firm about to disappear or one in the very early stages of growth. The answer, Marshall believed, was to identify a "typical" or representative firm. [See FIRM, THEORY OF THE.]

What is the typical market structure in Marshall's world? Nowhere in his work do we find the perfectly elastic demand curve of the current textbook version of perfect competition. It is clearly not monopoly (for Marshall reserves this case for special treatment), but it is doubtful whether, as has recently been suggested, the typical Marshallian market can be interpreted as monopolistically competitive in Chamberlin's sense. In spite of Marshall's remark that in the short run firms may have to lower price to increase sales, his basic view is that price is a parameter in the typical firm's plans.

Theory of distribution. Marshall's theory of distribution is outlined on two levels. On the assumption of fixed coefficients (such as Walras assumed in the first edition of the *Elements*), Marshall worked out his theory of joint demand. In this case there is no substitution within a given productive process; the principle of substitution is inoperative, and hence the marginal productivity theory is not applicable. To divide up the total product among the cooperating factors in the case of fixed proportions, Marshall used the law of derived demand: "The demand schedule for any factor of production

of a commodity can be derived from that of the commodity by subtracting from the demand price of each separate amount of the commodity the sum of the supply prices for corresponding amounts of the other factors" ([1890] 1961, vol. 1, p. 383). But at best this is a clumsy approach, and it did not represent Marshall's basic position. More generally he worked out a complete marginal productivity theory, and although he expressly denied that it was a theory of distribution, we must take this as typical Marshallian caution. His objections to regarding marginal productivity as a theory of wages were twofold: first, supply conditions must be included in the analysis; and second, to the extent to which labor and capital are in fixed proportions, it is not possible to identify the marginal product.

The concept of quasi rent, which filled an important gap in classical analysis, is also important for Marshallian distribution theory. Rent theory explained the return to fixed land, but there was nothing in classical analysis to explain the return to capital equipment already in existence. Marshall used the term "quasi rent" to explain rewards to any factors in inelastic supply and specifically applied the analysis to capital equipment in the short run. [See RENT.]

Equilibrium conditions. We have already discussed Marshall's division of the problem of price determination into a series of different time-period equilibrium positions. The general rule is that the longer the period of adaptation allowed, the more responsive is supply to price changes. To the extent to which long-run supply is perfectly elastic, Marshall saw a correlation with the classical cost-of-production theory of value. We have still to consider Marshall's conditions for market stability;

Figure 2

Figure 3

these appear to differ significantly from those laid down by Walras and Hicks, which are commonly studied in elementary dynamics. Marshall's conditions for a micromarket to be stable are as follows: (a) for quantity smaller than equilibrium quantity, demand price must be greater than supply price; (b) for quantity larger than equilibrium quantity, demand price must be less than supply price.

If a market that has "normal" demand and supply relationships, i.e., a downward-sloping demand curve and an upward-sloping supply curve, is stable in the Walras-Hicks sense, it is also stable in Marshall's sense. Divergences of interpretation occur, however, in other cases. Figure 2 shows a market where both stability conditions are satisfied. At price P_1 , which is above equilibrium, excess demand is negative (the Hicksian condition) and quantity bought is less than equilibrium, with demand price, OP_1 , greater than supply price, OP_2 . The market shown in Figure 3 is stable in terms of Marshall's conditions but unstable in terms of the Walras-Hicks conditions (e.g., for price above equilibrium it has excess demand).

Which specification is correct cannot be determined a priori but is a matter for empirical investigation. It is clear that the two solutions assume different behavioral reactions of buyers and sellers. More important, perhaps, the notion of a supply curve has to be specified much more carefully. [See DEMAND AND SUPPLY and ECONOMIC EQUILIBRIUM.]

Marshall also attempted to formalize and explain Mill's work on the conditions for equilibrium—and the suitability of equilibrium—in foreign trade. He did this by using the techniques of offer curves. His work in this field was not formally published until 1923, when parts of it were appended to his *Money, Credit & Commerce*. However, it was circulated privately, through the efforts of Henry Sidgwick.

Welfare economics. Marshall's contributions to welfare economics, while suggestive in terms of contemporary thought, contain some of his most doubtful analysis. Here Marshall relaxed his customary caution in the face of complex situations, in an effort to promote certain policy measures. In general his welfare economics supported the classical view that a regime of free markets maximizes welfare (utility). Marshall called this the doctrine of maximum satisfaction; his demonstration consisted of showing that for each micromarket the sum of surpluses is maximized. A monopolized market involves a suboptimal position because the sum of surpluses is lessened. The surpluses summed include both consumer and producer surpluses, or rents. In Figure 4 the free market price is P_0 with quantity Q_0 . The sum of consumer surplus and producer surplus is CAB . Let the market be monopolized and price and output be P_1, Q_1 ; total surplus is then reduced to $BCDE$. [See CONSUMER'S SURPLUS.]

However, Marshall stated two important exceptions to the doctrine of maximum satisfaction and free competition. First, he considered it to be an empirical fact that although utility is an increasing function of a person's real income, the rate of increase diminishes. As Marshall put it bluntly in the mathematical appendix to the *Principles*, "Every increase in his means diminishes the marginal degree of utility of money to him" ([1890] 1961, vol. 1, p. 838). Thus, it followed that, all other circumstances being the same, a redistribution of income from rich to poor would increase total satisfaction.

Much more important, perhaps, is Marshall's second ground for modifying the doctrine of max-

Figure 4

imum satisfaction. This is that satisfaction can be increased by taxing increasing-cost industries and subsidizing decreasing-cost industries. His analysis runs entirely in terms of consumer surplus, with all its weaknesses, and can easily be seen to depend on the slopes of the supply curves. However, the whole theory of externality and divergences between private and social benefits developed from Marshall's discussion, especially his exposition of the decreasing-cost case.

Monetary theory. Marshall is sometimes alleged to have neglected the monetary and, more generally, the aggregative framework within which his theory of value worked. This is a mistaken view. In his *Principles* Marshall is at pains to make clear that the core of that book presupposes a monetary framework, and he deals explicitly with this framework in other contributions. The two important sources for his views on money are *Money, Credit & Commerce*, written toward the end of his life, and, much more important, his *Official Papers*. This latter consists of a series of memoranda and evidence presented before royal commissions.

Official Papers contains the core of Marshall's monetary theory. The most important elements of his contributions in this area are the following: the so-called Cambridge equation and his development of a credit cycle through disequilibrium between real and monetary interest rates. Marshall is often regarded as the founder of the Cambridge approach to monetary theory. In essence, this theory postulates a stable demand function for money, with real income (or wealth) as the prime argument in the function. *Ceteris paribus*, such an approach will give a proportionate relationship between changes in the supply of money and changes in the general level of prices. [See MONEY, article on QUANTITY THEORY.] This approach was formalized by Pigou (1917) in a famous article [see the biography of Pigou] and elaborated by Keynes in his *Tract on Monetary Reform* (1923). Marshall made it absolutely clear, however, that changes in the other factors—in the volume of activity and the demand for money—may well dominate the relationship, especially in periods of economic crisis. His other contribution to the field is the spelling out of a mechanism connecting real and money rates of interest, through which divergences between the two generate a credit cycle.

The view, mentioned at the beginning of this article, that Marshall diverted economics from a proper consideration of macroeconomics is largely a result of Keynes's treatment of Marshall in *The General Theory* (1936). His treatment there con-

trasts widely with his assessment of Marshall's monetary economics in his famous obituary of Marshall. The reasons for this dramatic *volte-face* are complex and cannot be discussed here; all that can be said is that in retrospect the "Keynesian revolution" appears to be more an extension of the Marshallian tradition than an attempt to reverse it.

MARSILIUS OF PADUA

Marsilius of Padua (c. 1275-c. 1343) is known primarily as the author of the *Defensor pacis*, a bold antipapal tract dedicated to Emperor Louis IV of Bavaria in 1324 during his controversy with Pope John XXII. Although contemporary condemnations name John of Jandun as coauthor, internal evidence and incongruence with John's known political statements (Gewirth 1948) argue for its ascription to Marsilius alone. The *Defensor* is revolutionary in denying the clergy jurisdiction of any kind and in subordinating them completely to the state. The political concepts it brings to the support of these contentions are neither so "modern" nor so original as has sometimes been claimed. All are anticipated in some fashion somewhere in the long and complex medieval tradition. Yet, because Marsilius' argument leads him to special emphases, and because he richly develops, with ingenious use of Aristotle, ideas briefly enunciated by canonists and by other publicists, he is the first to present in elaborated theoretical form views that were to be fundamental to much of modern political thought. Even though the teaching of the *Defensor* is not free of ambiguity, no other medieval writing offers so vigorous or so complete a theory of popular sovereignty.

Jurisdiction in state and church. Marsilius argued that clerical pretensions to rule destroy the state (*civitas* or *regnum*), which, with its specialization of economic, military, governmental, and priestly "parts," is indispensable to "living and to living well." The survival of the state depends on effective government by a single unified "ruling part" (*pars principans*), and since the proper function of the clergy is not government but teaching (Christ having forbidden them all coercion), clerical rule of any sort, over anyone, destroys the unity of the government and deprives men of "the sufficient life." In this world divine law is without

direct sanction. It is only by authority of the human legislator that infractions can be brought to judgment.

All that is "truly law" on earth is the expression of the will of the legislator—the citizens of each community as a whole or their "weightier part" (*valentior pars*), the citizen body including all free adult males. The "weightier part" is weightier through "quality" as well as quantity of persons, but Marsilius argued that the more people who participate in legislation, the better the laws will be. Legislation by the multitude normally results in justice, because all but the singularly malicious or ignorant naturally wish to preserve the state and are able to discern the common benefit and to judge proposals. The legislator also establishes or selects the government or ruler. This may be one man or several but should in almost every instance be elective rather than hereditary. The legislator has the power to correct and even to depose the ruler. Although at times Marsilius seems to imply that the delegation of power to the ruler is all but absolute, his statements on correction and deposition are unequivocal.

Denying the divine institution of the papacy and of the episcopacy, Marsilius provides that in a Christian community the legislator select from candidates those to be priests and bishops, appoint them to pastorates, and control their exercise of office. A general council, elected by the several legislatures of the Christian world and composed of both clerics and learned laymen (the laymen voting if the clerics are not unanimous), determines the articles of faith. Only by decree of the human legislator do conciliar decisions become binding. For convenience the council or "the faithful human legislator without a superior" appoints a "head bishop" to act as president and executive secretary of the council. Custom alone argues the choice of the bishop of Rome. Although early in the *Defensor* Marsilius expressed a preference for a plurality of sovereign states, the idea of a "primary" or "universal" "faithful human legislator" and "a ruler by its authority" suggests the empire, and in the *Defensor minor* of 1342, written at the court of Louis, the "human legislator" becomes the "Roman prince."

Formation of Marsilius' views. In the molding of Marsilius' concepts the fifth book of Aristotle's *Politics* played a significant part. Also of importance in the genesis of his attitudes was his youth in Padua, a city sovereign *de facto*, republican in constitution, and often in conflict with the clergy. His being a physician and not a lawyer or theologian no doubt had much to do with the freshness

of his attack. Acquaintance with the work of French publicists seems probable from his years at the University of Paris, and familiarity with corporation law, from his position as rector of the university in 1313 (Lewis 1963, p. 564). Although he associated with Averroists, their influence on his ideas of church and state is impossible to ascertain.

Influence. Papal condemnations, including the excommunication of Marsilius (and John of Jandun) in 1327, established the reputation of the *Defensor* for the next three centuries. A principal charge in papal attacks on Wycliffe, and later on Luther, was that they borrowed Marsilius' doctrine. In the circumstances, conciliarist writers used the *Defensor* with caution. It was first printed (in Basel in 1522) to serve the Protestant cause, and in 1535 Thomas Cromwell paid most of the cost of printing an English translation. Through Richard Hooker, who cited it and shared some of its doctrines, it probably had an influence on John Locke, and so, indirectly, played an important part in carrying ideas of popular sovereignty from the medieval to the modern world.

MARX, KARL

Karl Marx (1818-1883) was born in Trier in the Prussian Rhineland. His alienation from his family when he had scarcely passed adolescence foreshadowed the social isolation of his later years.

His father, a lawyer, was as concerned as he was impressed with his son's "demonic genius," as he called it, and feared that young Marx's passion for poetry and philosophy would consume him both physically and morally. The elder Marx and his wife were Jewish, but for social reasons they were converted to Christianity. The younger Marx's awareness of his ethnic background aroused in him a certain self-consciousness; this may have been one source of his sense of marginality, his ambivalence toward society, and eventually of his conflicting qualities—thinker and prophet, scientist and moralist.

Although Marx received his doctorate in philosophy from the University of Jena at the age of 23, his association with the Young Hegelians, and with Bruno Bauer in particular, precluded his appointment to a university position in Germany. Indeed, Bauer lost his own post at the university in Bonn as a result of questioning the historicity of the New Testament. Marx thus became a "degraded bourgeois," deprived of a stable source of income and dependent for his livelihood and that of his wife and children on the generosity of his lifelong friend, Friedrich Engels, the son of a wealthy cotton manufacturer. (Marx's wife, Jenny von Westphalen, was of noble parentage but had no dowry.) At the age of 25, Marx left Germany and, except for a brief stay in Cologne in 1848-1849, lived the rest of his life in exile: in Paris from 1843 to 1845, in Brussels from 1845 to 1848, and finally in London. As early as 1845 he renounced his Prussian citizenship, and since he failed to acquire French citizenship by naturalization, for the greater part of his life he was something of a pariah.

Intellectual background. Marx's childhood and youth fall in that period of European history when the reactionary powers of the Holy Alliance were attempting to eradicate from post-Napoleonic Europe all traces of the French Revolution. There was, at the same time, a liberal movement in Germany that was making itself felt. The movement was given impetus by the July Revolution in France, and its chief representatives were the poets of the *Junge Deutschland*, among them Julius Borne and Heinrich Heine. In the late 1830s a further step toward radical criticism was made by the Young Hegelians, that group with which Marx became formally associated when he was studying law and philosophy at the University of Bonn.

Although he was the youngest member of the Young Hegelians—who included, in addition to Bauer, such thinkers as Ludwig Feuerbach, Arnold Ruge, and Moses Hess—Marx inspired their confidence, respect, and even admiration. They saw in him a "new Hegel," or rather a powerful and

Hegelian, who might successfully turn the dialectic of the master against his own conservative teachings in the fields of religion, politics, and law. Marx had already showed his determination to do so in his doctoral dissertation (1841), which dealt with the philosophical positions of Democritus and Epicurus, especially in the supplementary notes. He made his earliest attempt at a radical, albeit muted, criticism of Hegel, asserting, as Epicurus had argued against Democritus, that what is needed is a morally clear way of life rather than ideology or empty Epicureanism.

The intensive study of Spinoza, Leibniz, and Hume provided Marx with a spiritual armory for the rejection of a positive conception of democracy that was still being held at that time in Germany. It was from Spinoza rather than from Hegel that Marx learned to recognize the need for freedom. Therefore, when he rejected Hegel's metaphysics of the "State," Marx was well prepared to integrate a rational ethics with his own sociological and revolutionary doctrine. His early rejection of Hegel's political philosophy was unconditional and permanent, yet stripped of its "ideallistic" content, Hegel's logic continued to influence Marx as a way of analyzing his subject matter, namely society.

Marx's adherence to a radical view of democracy was also based on the study of such historical events as the revolutions in England, France, and America. From these historical studies he concluded that democracy must normally and inevitably culminate in communism, following a transitory stage of proletarian democracy (the "dictatorship of the proletariat"). After his conversion to communism Marx began his prolonged studies of economics, but while he was still developing from a liberal into a communist, he learned more from Spinoza and Feuerbach, Saint-Simon and Babeuf, Thomas Hamilton and Tocqueville, Weitling and Proudhon, Fourier, than from Smith or Ricardo.

Contributions to socialist thought. Although the epoch to which Marx belonged has its beginnings in the French Revolution, its historical dimensions coincide with those of the whole era of industrial and social revolutions and extend into our own time, hence the lasting appeal of a body of teachings that is by no means free from theoretical ambiguities.

The originality of Marx's thought lies in his intention to synthesize in a critical way the entire legacy of social knowledge since Aristotle. His purpose was to achieve a better understanding of the conditions of human development and with this understanding to liberate the active powers of man. His mind was moving toward an "associa-

tion, in which the free development of each is the condition for the free development of all" (1848). The desired system would be a communist society based on rational planning, cooperative production and equality of distribution and most important liberated from all forms of political and bureaucratic hierarchy.

This dual commitment—to scholarly understanding and to political action—created constant difficulty for Marx. He was often aware that his intense passion for reading and studying interfered with his activity on behalf of the political movement with which he identified himself. In his scholarly work the exposition and analysis are frequently interrupted by partisan outbursts of irony and sarcasm by bitter indictments of the capitalist class and the social system based upon its dominance.

Political economy was only one of the social-scientific disciplines that Marx intended to explore and then subject to criticism; the others were law, morals, and politics. He intended to treat each of these disciplines—and perhaps others also—in separate pamphlets. But the thoroughness with which he undertook his studies of the great economists and the delays in his scholarly work that arose from the need to make a living as a penny-a-liner prevented him from elaborating even one of these projects. *Capital* substituted *A Critique of Political Economy*, although a work of enormous dimensions is the fruit of only partially completed research. However, before the age of thirty Marx produced a number of works which together provide a remarkably adequate outline of his "materialist conception of history." Among these the most important are *The Holy Family* (1844), *The German Ideology* (in collaboration with Engels, 1845–1846), *The Power of Money* (1845), and *The Communist Manifesto* (1848). To these must be added an unfinished work first published in 1902 with the title *Economic and Philosophical Manuscripts of 1844* (see 1844), which shows with particular clarity the connections between the various ideas Marx was later to elaborate in *Capital*.

In these works Marx developed our first theory of society and history. He repudiated Hegelian and post-Hegelian speculative philosophy and building on Feuerbach's earlier program of criticism, he developed instead a historical theory based on a strictly scientific approach to historical phenomena. Drawing also on French materialism and on French empiricism and social communism, Marx's theory sought to explain all social phenomena in terms of their place and function in the complex systems of society and nature without recourse to what he considered metaphysical explanations—philosophical ideas. Clearly destined to these early

writings, this eventually became a mature sociological conception of the making and development of human societies.

At the beginning of *A Contribution to the Critique of Political Economy* (1859), Marx summed up in a dozen aphorisms the general results of the investigation he had undertaken in the 1840s and asserted that these results were the "guiding thread" of his further studies. Here are the beginning and the end of this justifiably celebrated and controversial passage:

In the social production which men carry on they enter into definite relations that are indispensable and independent of their will; these relations of production correspond to a definite stage of development of their material powers of production. The sum total of these relations of production constitutes the economic structure of society—the real foundation, on which rise legal and political superstructures and to which correspond definite forms of social consciousness. The mode of production in material life determines the general character of the social, political and spiritual processes of life. It is not the consciousness of men that determines their existence, but, on the contrary, their social existence determines their consciousness. . . . In broad outlines we can designate the Asiatic, the ancient, the feudal, and the modern bourgeois methods of production as so many epochs in the progress of the economic formation of society. The bourgeois relations of production are the last antagonistic form of the social process of production . . . ; at the same time the production forces developing in the womb of bourgeois society create the material conditions for the solution of that antagonism. This social formation constitutes, therefore, the closing chapter of the prehistoric stage of human society. ([1859] 1913, pp. 11–13)

Marx's "materialistic method" is well exemplified by his treatment of the concept of "alienation"—a spiritual concept in Hegel's philosophy that had already been modified in Feuerbach's anthropology. In the "Paris Manuscripts of 1844" (1844a), Marx conceived of alienation as a phenomenon related to the structure of those societies in which the producer is divorced from the means of production and in which "dead labor" (capital) dominates "living labor" (the worker). A systematic elaboration of the concept appears in *Capital* under the heading "fetishism of commodities and money." But the ethical germ of this conception can be found as early as 1844 in the two essays Marx published in the *Deutsch-französische Jahrbücher*: "On the Jewish Question" (1844b) and "Contribution to the Critique of Hegel's Philosophy of Right" (1844c). There Marx unequivocally rejected and condemned "the state" and "money," and he invested the proletariat with the "historical mission" of emancipating society as a whole. The identity of Marx's early

political views with the theoretical analysis in *Capital* is evident in the manner in which the argument of *Capital* is brought to a close. Describing the "historical tendency of capital accumulation," Marx quoted the prophetic statement in the *Communist Manifesto*: "What the bourgeoisie . . . produces, above all, are its own gravediggers. Its fall and the victory of the proletariat are equally inevitable." Similarly, in ending the preamble of his inaugural address to the International Working Men's Association (1864), Marx launched the same summons that ends the *Manifesto*: "Workers of all countries, unite!"

Although this summons seems to contradict his assertion of the "historical necessity" of communism, in the very real unity of sociology and ethics the contradiction vanishes. The proletariat is enjoined to unite in order to transform society, and its recognition of the consequences of such unity for the achievement of its historical mission becomes part of the "historical necessity" of the process; by this recognition, the proletariat confirms the process.

In accordance with the maxim, formulated in his "Theses on Feuerbach" (1845b), that man must prove the truth of his thinking in practice, Marx neglected his scientific work for long periods in order to participate in the class struggles of his time. He did so not without regret, for he considered his scholarly studies the most valuable form of participation in the social struggle. His more direct intervention was, of course, mainly literary in character—his several hundred articles in German, British, and American newspapers and journals; and the various addresses and manifestoes he wrote for the Working Men's International. Among his writings on the political events of his time are some unquestionable masterpieces of this genre: *The Class Struggles in France* (1850); *The Eighteenth Brumaire of Louis Bonaparte* (1852); *Secret Diplomatic History of the Eighteenth Century* (1856); *Herr Vogt* (1860); "Address" to the First International (1864); *The Civil War in France* (1871); the *Critique of the Gotha Programme* (1875). In every line he wrote, whether intended for publication or not, his ultimate singleness of purpose is clearly evident.

This is particularly true of his magnum opus, *Capital*, whose scope transcends its outline of political economy as well as its critique of economics. At the same time that Marx defined the ultimate aim of the work as "[laying] bare the economic law of motion of modern society," he had in mind a thorough and systematic criticism of a type of society, namely capitalism. In spite of its truncated

character, *Capital* is monumental in its construction and grandiose in its purpose. It is in *Capital* (even more than in Marx's philosophical writings) and particularly in the posthumously published *Grundrisse* (1857–1858), that the serious student will find the key to Marx's dialectical method as it contrasts with the method of Hegel. Moreover, *Capital*, to a greater extent than Marx's political writings, reveals the reason for the celebrated "failure" of Marxian predictions: the reason lies not so much in the inadequacy of Marx's social and economic theory as in the expectations he based on it. However, in the last analysis these expectations rest on the individual search for perfection and liberty.

Marx's influence. Marx's teachings have been expanded and diffused in two ways that are, in effect, opposed to each other. The first is "Marxism" as an ideology, i.e., a dogmatic systematization of Marx's ideas for political purposes, expressed as party doctrine or state religion, and disseminated by its supporters; the second form is a growing body of research and scholarly activity in various branches of the social sciences that has been illuminated by Marx's theoretical discoveries. When Marx himself noticed that his admirers were showing the first signs of "Marxism," he rebuked them unequivocally and asserted, as Engels reported in several letters (e.g., to Bernstein and Conrad Schmidt): "I am not a Marxist." However, he tolerated and even supported Engels' efforts to win acceptance for *Capital* in academic circles. Inadvertently, Engels thus became the first "Marxist" and the cofounder of the Marxist ideology, whose manifesto was Engels' *Anti-Dühring* (1878). Marx was thereafter acclaimed as the founder of the new science of socialism and was credited by Engels with two scientific discoveries—the materialistic concept of history and the theory of surplus value.

Engels' efforts to popularize Marx's ideas led to the schematization of some of Marx's basic propositions; he claimed to have extended Marx's methodological and critical approach, so that it embraced nature as well as history. With their followers, the distortion of Marx's thought went further still. While Marx considered his general theory to be a scientific method of investigating the transient nature of every economic system and placed his confidence in proletarian class consciousness as an agency of change, "Marxism," particularly in its Leninist version, has become a party ideology. This transformation is reflected in the substitution of the coercive direction of political elites for the spontaneous activity and con-

sciousness of the producing class; paradoxically, these "Marxist" elites have transformed Marx's theoretical propositions into norms of political action.

The relevance of Marx's theories for the social sciences has been the subject of much fruitful debate. In a kind of osmotic process, Marx's theories have been incorporated into the social sciences at the same time that they have stimulated important countertheories. A significant event in this process was Sorel's critique of Durkheim (Sorel 1895), in which he praised the "materialist theory of sociology" according to which the various social systems—political, philosophical, religious—must be considered as interdependent and as having a common base; Sorel believed that what Marx assigned to sociology as its major subject for investigation was the underlying system of production and exchange and the conflict of classes.

Marxist social science developed in Germany, stimulated by the work of Rudolf Stammler (1896), and it was in response to Stammler that Max Weber began his influential studies of the Marxian thesis concerning the relationship between the economy and other social institutions. In Italy Marxist theories were discussed in several universities under the leadership of Antonio Labriola, Giovanni Gentile, and Benedetto Croce, and in France such discussions were stimulated by François Simiand. Thomas G. Masaryk, while he was a university professor in Prague, produced a large work of analysis and criticism of Marx's sociological method and hypotheses (1898). The international character of the "debate with the ghost of Marx" may be further illustrated by the fact that in tsarist Russia numerous books and periodicals paid increasing attention to "scientific socialism" even before Plekhanov and Lenin appeared on the scene. In the United States the influence of Marx's ideas is evident in the writings of Albion W. Small, George H. Mead, Thorstein Veblen, and Joseph Schumpeter, among others.

Since World War I, Marx's theories have not only stimulated sociological work in general but have also given impetus to a new field of sociological inquiry, the sociology of knowledge, exemplified by the works of Max Scheler and Karl Mannheim.

The process of incorporating Marx's ideas into the social sciences in Western countries contrasts vividly with the unsure attempts by "Marxist" regimes to invent and decree a "Marxist" sociology. The efforts of these regimes unwittingly confirm one of Marx's major hypotheses—that the dominant ideas of a society are those of its ruling class.

MARX'S WRITINGS

WORKS BY MARX

- (1841) 1927-1929 *Über die Differenz der demokratischen und epikureischen Naturphilosophie*. Pages 3-144 in Karl Marx and Friedrich Engels, *Historisch-kritische Gesamtausgabe: Werke, Schriften, Briefe*. Section 1, Volume 1, part 1: Werke und Schriften bis 1844. Frankfurt am Main (Germany): Marx-Engels Verlag. → Written in 1841, the text with some notes was first published posthumously in 1902.
- (1843) 1953 *Kritik des hegelischen Staatsrechts*. Pages 20-149 in Karl Marx, *Die Frühschriften*. Stuttgart (Germany): Kröner.
- (1844a) 1964 *Economic and Philosophic Manuscripts of 1844*. New York: International Publishers; London: Lawrence & Wishart. → Written in 1844 but first published posthumously in German in 1932. Sometimes referred to as the "Paris Manuscripts of 1844."
- (1844b) 1963 *On the Jewish Question*. Pages 1-40 in Karl Marx, *Early Writings*. London: Watts. → First published in Volume 1/2 of the *Deutsch-französische Jahrbücher*.
- (1844c) 1963 *Contribution to the Critique of Hegel's Philosophy of Right: Introduction*. Pages 41-59 in Karl Marx, *Early Writings*. London: Watts. → First published in Volume 1/2 of the *Deutsch-französische Jahrbücher*.
- (1844d) 1963 *Early Writings*. Translated and edited by T. B. Bottomore. London: Watts. → First published in German. Contains "On the Jewish Question"; "Contribution to the Critique of Hegel's Philosophy of Right"; and "Economic and Philosophic Manuscripts."
- (1845a) 1956 *The Holy Family*. Moscow: Foreign Languages Publishing House. → First published as *Die heilige Familie*.
- (1845b) 1935 *Theses on Feuerbach*. Pages 73-75 in Friedrich Engels, *Ludwig Feuerbach and the Outcome of Classical German Philosophy*. New York: International Publishers. → First published in German.
- (1845-1846) 1939 MARX, KARL; and ENGELS, FRIEDRICH *The German Ideology*. Parts 1 and 3. With an introduction by R. Pascal. New York: International Publishers. → Written in 1845-1846, the full text was first published in 1932 as *Die deutsche Ideologie* and republished by Dietz Verlag in 1953.
- (1847) 1963 *The Poverty of Philosophy*. With an introduction by Friedrich Engels. New York: International Publishers. → First published as *Misère de la philosophie*.
- (1848) 1964 MARX, KARL; and ENGELS, FRIEDRICH *The Communist Manifesto*. New York: Washington Square Press. → First published in German.
- (1849) 1962 *Wage Labour and Capital*. Volume 1, pages 74-97 in Karl Marx and Friedrich Engels, *Selected Works*. Moscow: Foreign Languages Publishing House. → First published as "Lohnarbeit und Kapital" in the *Neue Rheinische Zeitung*.
- (1850) 1964 *The Class Struggles in France: 1848-1850*. New York: International Publishers. → A series of

articles first published as "Die Klassenkämpfe in Frankreich 1848 bis 1850" in the *Neue Rheinische Zeitung: Politisch-ökonomische Revue*.

- (1852) 1964 *The Eighteenth Brumaire of Louis Bonaparte*. New York: International Publishers. → First published in German.
- (1856) 1899 *Secret Diplomatic History of the Eighteenth Century*. Edited by Eleanor Marx Aveling. London: Sonnenschein. → First published as "Revelations of the Diplomatic History of the Eighteenth Century" in the *Sheffield Free Press*.
- (1857-1858) 1953 *Grundrisse der Kritik der politischen Ökonomie*. Berlin: Dietz. → Written in 1857-1858; first published posthumously by the Marx-Engels-Lenin Institute, Moscow, in 1939-1941. A partial English translation was published in 1965 as *Pre-capitalist Economic Formations* by International Publishers.
- (1857-1859) 1959 MARX, KARL; and ENGELS, FRIEDRICH *The First Indian War of Independence: 1857-1859*. Moscow: Foreign Languages Publishing House. → A collection of articles written for the *New York Daily Tribune*. Also includes articles dated 1853 and notes from a manuscript of the 1870s.
- (1859) 1913 *A Contribution to the Critique of Political Economy*. Chicago: Kerr. → First published as *Zur Kritik der politischen Ökonomie*.
- (1860) 1953 *Herr Vogt*. Berlin: Dietz.
- (1861-1863) 1952 *Theories of Surplus Value: Selections*. New York: International Publishers. → A selection from the volumes first published between 1905 and 1910 as *Theorien über den Mehrwert*, edited by Karl Kautsky, taken from Karl Marx's preliminary manuscript written between 1861-1863 for a projected fourth volume of *Capital*.
- (1861-1866) 1961 MARX, KARL; and ENGELS, FRIEDRICH *The Civil War in the United States*. 3d (Centennial) ed. New York: International Publishers. → A paperback edition was published in 1964 by Citadel Press.
- (1864) 1937 *Address and Provisional Rules of the Working Men's International Association*. Pages 27-44 in *Founding of the First International: A Documentary Record*. New York: International Publishers.
- (1867-1879) 1925-1926 *Capital: A Critique of Political Economy*. 3 vols. Chicago: Kerr. → Volume 1: *The Process of Capitalist Production*. Volume 2: *The Process of Circulation of Capital*. Volume 3: *The Process of Capitalist Production as a Whole*. The first volume was published in 1867. The manuscripts of Volumes 2 and 3 were written between 1867 and 1879. They were first published posthumously in German in 1885 and 1894.
- (1871) 1963 *The Civil War in France*. With an introduction by Friedrich Engels. Moscow: Foreign Languages Publishing House. → First published in English. A paperback edition was published in 1964 by International Publishers.
- (1875) 1959 MARX, KARL; and ENGELS, FRIEDRICH *Critique of the Gotha Programme*. Moscow: Foreign Languages Publishing House. → Written by Marx in 1875 as "Randglossen zum Programm der deutschen Arbeiterpartei." First published with notes by Engels in 1891.
- SELECTIONS FROM MARX'S WORKS
- Die Frühschriften*. Stuttgart (Germany): Kröner, 1953.
- Marx on China, 1853-1860: Articles From the New York Daily Tribune*. With an introduction and notes by Dona Torr. London: Lawrence & Wishart, 1951.
- MARX, KARL; and ENGELS, FRIEDRICH *Revolution in Spain*. New York: International Publishers, 1939. → A collec-

tion of articles first published in the *New York Daily Tribune*, *Putnam's Magazine*, the *New American Encyclopedia*, and *Der Volksstaat*.

MARX, KARL; and ENGELS, FRIEDRICH *The Russian Menace to Europe: A Collection of Articles, Speeches, Letters and News Dispatches*. Edited by Paul W. Blackstock and Bert F. Hoselitz. Glencoe, Ill.: Free Press, 1952. → Contains materials written between 1848-1894.

MARX, KARL; and ENGELS, FRIEDRICH *Karl Marx and Frederick Engels on Britain*. Moscow: Foreign Languages Publishing House, 1953. → Contains a collection of the most important writings of Marx and Engels, written between 1844-1895, dealing with England.

MARX, KARL; and ENGELS, FRIEDRICH *Karl Marx and Frederick Engels: Letters to Americans 1848-1895: A Selection*. New York: International Publishers, 1953.

MARX, KARL; and ENGELS, FRIEDRICH *Karl Marx and Frederick Engels: Selected Correspondence*. Moscow: Foreign Languages Publishing House, 1956. Contains material dated 1843-1895.

MARX, KARL, and ENGELS, FRIEDRICH *On Colonialism*. Moscow: Foreign Languages Publishing House, 1960. → Contains a collection of works by Marx and Engels written between 1850-1894.

MARX, KARL; and ENGELS, FRIEDRICH *Selected Works*. 2 vols. Moscow: Foreign Languages Publishing House, 1962.

Selected Writings in Sociology and Social Philosophy. 2d ed. Edited by T. B. Bottomore and M. Rubel, with a foreword by Erich Fromm. New York: McGraw-Hill, 1964. → Contains works written by Marx between 1844-1875

COLLECTED WORKS

MARX, KARL; and ENGELS, FRIEDRICH *Historisch-kritische Gesamtausgabe: Werke, Schriften, Briefe*. 12 vols. Edited by David Rjazanov and V. Adoratskij, commissioned by the Marx-Engels Institute, Moscow. Frankfurt am Main, Berlin, and Moscow: Marx-Engels Verlag, 1927-1935.

MARX, KARL; and ENGELS, FRIEDRICH *Karl Marx, Friedrich Engels: Werke*. Vols. 1-. Berlin: Dietz, 1956-. → Volumes 1-19, 22-31 of a contemplated 36-volume edition.

MARXISM

This article deals with the origins and development of the political doctrine of Karl Marx. Marxism is also discussed in ECONOMIC THOUGHT, article on SOCIALIST THOUGHT; MARXIST SOCIOLOGY; SOCIALISM; and in the biography of MARX. Contemporary political and economic aspects are discussed in COMMUNISM; COMMUNISM, ECONOMIC ORGANI-

ZATION OF. Also related are PLANNING, ECONOMIC, article on EASTERN EUROPE; WORKERS. The biographies of BERNSTEIN; ENGELS; FANON; KAUTSKY; LANGE; LENIN; LUKÁCS; LUXEMBURG; MAN; MILLS; OSSOWSKI; and TROTSKY describe different intellectual developments after Marx. For the biographies of other socialist thinkers, see under SOCIALISM.

Like other schools of socialism that arose in the early nineteenth century, Marxism was a response to the economic and social hardships accompanying the growth of Western industrial capitalism. If in recent decades it has attracted most of its adherents in countries hardly touched by industrial capitalism, this is the result of a tortuous ideological history.

The intellectual heritage from which Marxism drew its insights, attitudes, and concepts is a synthesis of many ideological currents of the early and middle nineteenth century. They include the basic assumptions of the democratic faith and the slogans of the French Revolution; indeed, Marxism asserts that this revolution was betrayed by the very class which made it and will only be fulfilled by the proletariat through socialism. Hence, Marxism also embraces the syndrome of attitudes associated with workers' protest movements and socialism. Further, Marxism embodies the empiricism or "materialism" of Bacon, Hobbes, and Helvétius. From Rousseau and the romantics it has taken a strongly ambivalent attitude toward past and present institutions, together with a strong commitment to historicism and its Hegelian form—dialectics. Finally, this mixture is seasoned with the anthropocentrism of Feuerbach, the economic doctrines of Smith and Ricardo, and the class-war theories of Michelet and other historians of the French Revolution.

As a syndrome of attitudes, Marxism might be described as a synthesis of radicalism, optimism, and a commitment to science: it is radical in criticizing contemporary social institutions and practices as stupid and inhuman; it is optimistic in expecting, eventually, the creation of a "good society" worthy of man's highest potentials; it is committed to science not only because it wishes to analyze society but also because it is convinced that the scientific investigation of the social forces active in the contemporary world will confirm both its radicalism and its optimism.

Doctrine

Marxism is a dialectical theory of human progress. It regards history as the development of man's effort to master the forces of nature and, hence, of

production ("economic interpretation of history"). Since all production is carried out within social organization, history is the succession of changes in social systems, the development of human relations geared to productive activity ("modes of production"), in which the economic system forms the "base" and all other relationships, institutions, activities, and idea systems are "superstructural."

History is progress because man's ability to produce, his "forces of production," continually increase. It is regression because in perfecting the forces of production man creates a more and more complex and oppressive social organization, seemingly beyond human control (the "production relations"), the central feature of which is the division of society into classes. Classes are defined by their relations to the essential means of production: the ruling class is that group of men who own the means of production; those who are propertyless are forced to function as the laboring class. Like Rousseau, Marx was profoundly interested in exploring the inequalities of men because he shared his belief that there can be no democracy as long as there are inequality and special interests.

Progress, thus, is a mixed blessing. Nor is it unilinear, for in the history of man different elements of the complicated social system continually become dysfunctional to each other. In particular, the production relations, originally in tune with a given state of the forces of production, lag behind the latter and come to retard their further development. From a promoter of progress the ruling class turns into a useless parasite. But when the old production relations have turned into a dead shell, mankind assures the march of progress by remaking the social system in revolutionary violence, giving leadership to the class wielding the most advanced means of production. According to the Marxist scheme of history, mankind has gone through three or four major modes of production since an initial golden age of primitive communism: ancient slave society, feudalism, and capitalism (to which Marx added, in some of his works, Asiatic society as a distinct mode of production).

Capitalism, the last form of society torn by a class struggle, represents the peak of human development so far. On the one hand, it has created and amassed unprecedented wealth, which, if used rationally, could assure the material well-being of all mankind. Yet, by virtue of its own laws of operation, capitalism cannot utilize its means of production rationally but must match the accumulation of capital with the accumulation of misery and chaos. Again, while it has promoted constitutional government and the rights of man, the

formal rights and equalities of liberal regimes are vitiated by actual inequalities and ultimate dehumanization: formally free, man has been converted into a commodity, whose labor power, talents, and personality are for sale on the free market. The resolution of these contradictions will be produced by capitalism itself. Its own economic laws not only produce chaos and crisis but also narrow the social basis of capitalism by casting the mass of the population into the proletariat. At a crisis point the exploited will rise in revolution, expropriate the ruling class, replace commodity production with an economy based on national planning, and abolish all class divisions in society.

Supporting the optimistic prognosis of revolutionary Marxism is the image of the proletariat as the "chosen people," who, because of their place in society, their state of organization, and their spontaneous grasp of reality ("class consciousness") can be expected to rise above all narrow interests, loyalties, and ideologies and liberate mankind forever from the curse of property and class.

Development

Marxist doctrine was spelled out concisely in the *Communist Manifesto*. This pamphlet was written shortly before the outbreak of the 1848 revolution, which Marx and Engels were confident would lead to the socialist revolution of the proletariat. The failure of 1848 forced them to explain what had prevented this act of deliverance. In subsequent political commentaries, they emphasized complicating factors left out of the more abstract analysis of capitalism: the role of precapitalist classes in European politics, especially the petty bourgeoisie; the baneful role of demoralized workers (*Lumpenproletariat*); the role of the state as an independent political force; and the role of nations. Many ideas contained in these political writings were never fully integrated with general Marxist theory. Indeed, Marx's major work on the capitalist system remained a fragment; and he died before he had time to give a systematic presentation of such a central concept as social class.

Another task made necessary by the failure of 1848 was to elaborate a political strategy for the proletarian movement. Here Marxism came to emphasize the differences between long-range and short-range objectives. Socialism was defined as the maximal goal, while the minimal goal was the liberation of capitalism from feudal and absolutist residues of a political, economic, or social nature. A more intermediate goal—the dictatorship of the proletariat—received scant mention in Marx's writings.

Problems of political strategy became more important because, after inauspicious beginnings, Marxist doctrine was in time accepted as the party ideology of the European labor movement. There is irony in this merger because the workers' movement which finally accepted Marxist ideology was in many ways different from the proletariat as Marx and Engels had described and idealized it in 1847-1848. It tended toward reformism, had faith in constitutional democracy, and, as the first mass party of modern history, became thoroughly bureaucratized. Ulam (1960) cogently argues that Marxism at that time was no longer a suitable ideology for the European labor movement. Hence, its adoption raises puzzling questions which cannot be pursued here.

Suitable or not, the merger of the ideology with the movement was a turning point because, with it, Marxism became a formal ideology, a guide to thought and action, a holy writ and catechism. Henceforth, it tended toward doctrinal rigidity. The growing discrepancy between revolutionary theories and actual party policies lent Marxism a note of hypocrisy, while a widening gap between assumptions and reality had the effect of ideological blinders on those who wanted to use Marxism as a tool for comprehension. Moreover, once Marxism was accepted as party doctrine, its adherents, beginning with Engels, extended the doctrine into areas of inquiry to which Marx himself had not applied it. Marx had thought to encompass with his theory contemporary society and all of human history. Engels sought to integrate Darwinian theory and all natural science with Marxism and to raise Marxist theories to the level of a universal philosophy. For Marx the ultimate determinant of the course of history was man and his needs, but for Engels it came to be matter and its motion. Yet, it was the ideas of Engels which set the tone for orthodox Marxism of both the social democratic and communist persuasions. The sociopsychological dynamics behind both this extension of the doctrine and its transformation into a holy writ still need to be explored.

Conflicting interpretations

As soon as Marxism was accepted as the doctrine of the European labor movement, it became a matter of controversy among its followers, partly because the work of Marx and Engels had remained unfinished in many details, but even more because of social changes that had occurred. The ensuing debates dealt with issues of strategy, focusing on the problem of maturity, i.e., the task of defining the point at which a society might be

ripe for the proletarian revolution. Engels alluded to the problem by wondering about the paradox that the proletarian revolution might be impossible as long as it was necessary and unnecessary once it became feasible. Problems of organization and tactics also provided material for controversies. Discussions of these and many related issues are still going on within Marxism, even though the same questions are asked in changing circumstances.

Of the controversies raging before World War I, the bitterest was unrelated to strategy or organization. It arose instead out of the growing unrealism of Marxist doctrine. The spread of economic prosperity and constitutional government belied Marxist prognoses about the intensification of crises and misery; and the revolutionary slogans of the *Communist Manifesto* sounded incongruous when uttered by the moderate leaders of the Second International.

To resolve the discrepancy, the "revisionists" proposed a thoroughgoing change of Marxist doctrines so as to make them reflect current conditions, modern scientific insights, and social democratic aims and policies. Revisionism came close to being a repudiation of Marxist ideas; and it can be regarded as the first in a long series of steps away from Marx made by democratic socialists since the turn of the century. Their antagonists in the Second International insistently upheld the letter of Marxist doctrines, identifying loyalty to the writ of Marx with loyalty to the workers' movement. The method of bridging the gap between theory and reality was by denying its existence, meanwhile reinterpreting Marx's revolutionary theories so as to make them yield reformist counsel. For most Marxists committed to democratic socialism, this was an ideological rear-guard action, because the predominant trend in the socialist movement has been to follow the revisionists in their repudiation of Marx.

While the revisionists sought to change theories in order to align them with reality and the orthodox denied the need for such realignment, a radical wing of the Marxist movement, which arose after the turn of the century, attempted to bridge the gap between theory and practice by leading the workers' movement back to the revolutionary orientation of the *Communist Manifesto*. This wing became the nucleus of communism; most of its leaders joined communist parties, if only for short periods.

The radical Marxists asserted that despite profound changes in the capitalist world since the days of Marx—especially "imperialism" (the export of

capital and of capitalism to dependent countries overseas)—the basic contradictions of capitalism had remained; hence also the inevitability and necessity of the revolution Marx had predicted. Disagreements among the radicals arose over many issues, the most divisive one being the question of organization. One faction, of which Rosa Luxemburg was the outstanding spokesman, saw the roots of "reformism," i.e., democratic socialism, in the bureaucratization of the workers' movement, which they thought stifled revolutionary initiative and proletarian class consciousness. Against them, Lenin and his Bolsheviks believed that revolution making should be subject to rational management (bureaucracy), and they held, moreover, that by itself, spontaneously, the proletariat would not be able to attain class consciousness; hence their emphasis on leadership by an enlightened elite organized in bureaucratic fashion in the party, which should function as the general staff of the proletarian revolution. Leninist Marxism thus focuses on the task of manipulating the masses through leaders who have acquired insight into the politically necessary and possible by applying Marxist categories to the analysis of their society.

New ideological problems were bound to arise when a Marxist party was founded in Russia toward the end of the nineteenth century, because most of the conditions to which Marxism originally had been a response were absent in that country. The very fact that Marxism could find acceptance among Russian revolutionaries is an interesting ideological development, which deserves explanation in another context. Russia's economic backwardness and repressive political system exacerbated problems of timing, leadership, organization, political alliances, and related issues, considerably straining the entire framework of Marxist concepts. For instance, the notion that the bourgeoisie cannot fulfill the ideological promises of the bourgeois revolution was a central tenet of Marx and Engels. But Lenin's idea that the bourgeoisie will not carry out or even initiate "its own" revolution (which will instead have to be accomplished by the proletariat and its allies) requires very bold use of Marxist class terminology. In its mature form Bolshevism takes even greater liberties with the original Marxist conception when it assigns to colonial and other dependent nations a significant role in the hoped-for "proletarian" revolutions. Underdeveloped nations here assume some of the traits which Marx had attributed to the industrial workers of the West. But as a consequence, the "proletarian revolution" itself turns into something very different from what Marx had assumed

it to be. Originally thought of as the act of taking over the mature industrial establishment created (and mismanaged) by capitalism, it now can take over nothing but a backward economy and culture; this leads to the paradoxical conclusion that the proletarian state (a "superstructural" phenomenon) will have to begin constructing its own economic "base," making use of "capitalist" methods in doing so.

In their controversies over policy and organization, the different factions of Russian Marxism emphasized those portions of the ideology which seemed to support their views, at the expense of other portions. Lenin and his Bolsheviks were so intent on reaching their goal, the proletarian revolution, that they amended Marx's revolutionary timetable beyond recognition; this led to the accusation that they were Blanquists rather than Marxists. The more cautious Mensheviks, in turn, seemed so concerned with following the timetable provided by Marx that Lenin accused them of postponing socialism and the revolution *ad calendas Graecas* and thus betraying the cause of the proletariat.

The schism which split Russian Marxism into two hostile social-democratic parties was extended to the entire world-wide movement in the years from 1914 to 1920. Disagreements over the proper attitudes a Marxist should take toward the war and the Russian Revolution divided Marxism irreconcilably into socialists and communists, each creating their own international federation of parties. The most important issue between them was their difference of attitude toward the Bolshevik seizure of power and method of governing. The communists regarded their state as the pioneer of the international workers' movement. The socialists saw in it an ill-timed and irresponsible adventure which discredited the Marxist movement. In subsequent decades, the communist-socialist split hastened the process by which democratic socialism came to dissociate itself from Marxist ideology. [See SOCIALISM.]

Marxism as the ideology of a ruling party

Once in power, the Russian communists sought to use Marxism as a guidebook for the further road toward socialism and for managing a proletarian dictatorship. The difficulties they encountered and the sketchiness of the hints Marx and Engels had provided for solving these problems led to new and sharp controversies among the communists themselves, in which the broadest spectrum of Marxist concepts was once again discussed from divergent points of view. With Stalin's rise to power

the debate was forcibly closed, and his own views were imposed as dogma over all communist parties. The substance of this dogma, based on Leninist principles, might be summarized as follows: Marxism is both scientific truth and ideology—the ideology of the working class. The Communist party alone possesses full scientific insight and expresses the true interests of the workers. Hence, only he who is loyal to the party can be loyal to the proletariat, in tune with the course of history, or capable of grasping the truth. Nothing can be true which contradicts the party. Further, official Soviet doctrine justifies the communist state, its policies and social structure, as a proletarian dictatorship and a true democracy engaged in “constructing socialism.” Marxism here has turned into a theory of state defending, as virtually perfect, a regime violating all the libertarian and egalitarian values expressed by Marx. The success with which Marxist concepts have been used to fashion a conservative and authoritarian doctrine of this kind is a major achievement in ideology making. In the Soviet Union this has recently been supplemented by a program for the “transition to communism,” which is an obvious attempt to tone down expectations. Calling for little significant change in present-day Soviet society, it signals the withering away of utopia on this branch of Marxist ideology. Finally, contemporary communist ideology incorporates a program for the further spread of the “proletarian” revolution. But although the workers in the industrialized countries have not been written off formally, in effect the communist movement has now substituted the colonial and other dependent nations in the historic role which Marx attributed to the proletariat of the capitalist world.

The function of the ideology in communist political systems has been the subject of much controversy. Many scholars (echoing communist dogma) see Marxism-Leninism as the master plan guiding all communist thought, actions, and institutions. Others assert that it is no more than rationalization which easily adapts to any changes in policy. However contradictory, both theories have some plausibility but are easily refuted in their exaggerated forms.

Marxist ideology, as amended by Lenin and his successors, did inspire the men who made communist revolutions and has influenced communist regimes and institutions even more directly than the ideas of Rousseau and Locke have shaped the institutions of the French and American republics. Although the ideology becomes primarily rationalization after the communist seizure of power, it

does remain the language of politics, meaning not only a code of communications for the political elite but also the conceptual frame of reference used for cognitive and ethical self-orientation. It thus determines both analysis and action, if only negatively, that is, as ideological blinders and as a brake (“bad conscience”) on freedom of action. [See IDEOLOGY.]

A doctrine which is meant to serve as a useful aid to cognition must be realistic and flexible, whereas a doctrine functioning as a communications code need only be rigid. These and other conflicting functions of the ideology strain it. Primarily, perhaps, the ideology functions as a legitimization device, implying not only an exercise in public relations to attain legitimacy among the citizens but, even more important, a continual attempt by the party leaders to convince themselves of their own legitimacy; more generally, it functions as an ideological exoskeleton for insecure bureaucrats in a vast and powerful administrative machine. The implication is that communist leaders in making doctrinal pronouncements speak more to themselves than to their citizenry, and least of all to the outside world. This phenomenon of self-encouragement or self-legitimation, observable in all societies, has been unduly neglected by contemporary communications theory.

Ideological strains

Since World War II, communist parties have come to power in close to a dozen countries of eastern Europe, Asia, and the Caribbean area. These various Marxist-Leninist regimes came to power by widely divergent methods and, once installed, faced very different tasks because of the great differences in the cultures, economic development, political traditions, and social structures of the countries concerned. If to these variations in national interests and outlooks of the several communist regimes one adds the bitter memory of past disagreements and injuries, plus the normal political rivalries between groups and personalities within a large group of states, it is not astonishing that sharp conflicts arose in the communist camp, straining relations between the different regimes and within each communist party. Given the relations between politics and ideology within the communist movement, these disagreements sooner or later had to become doctrinal and thus turned into questions of fundamental principle. Hence, the dialogue between Tito and Stalin, between Khrushchev and Mao, and between revisionists and dogmatists in every communist party led to a discus-

sion of not only basic problems in revolutionary strategy and socialist construction but also of the most fundamental concepts of Marxism-Leninism.

The resulting differences within the communist world are today as deep as the schism between Mensheviks and Bolsheviks half a century ago. Moreover, the issues under discussion are similar to those which divided Russian Marxism at that time, even though the circumstances and the concrete reference points have changed. The unity of the communist movement is as irretrievably gone as was the unity of European Marxism at the time of the October Revolution. As a result, what 15 years ago seemed well-established dogma is now subject to doubt. Within some of the communist societies, party dogmas today are also being criticized in the name of science, while the practices of communist governments and the rhetoric which justifies them are challenged in the name of Marxist humanism. In short, official ideology is assailed from several directions. Two tendencies are likely to result from this multiple onslaught. Official ideological output may turn increasingly into empty, meaningless political oratory, ritually incanted on suitable ceremonial occasions but as removed from life as Sunday sermons and Independence Day speeches. At the same time, a genuine dialogue conducted between and within the several communist parties over a sufficient period of time might serve to reinvigorate Marxist ideology, especially in communist parties that have not yet come to power, even though it may also lead many former adherents to repudiate this ideology. [See the articles under COMMUNISM.]

Marxism in the noncommunist world

Although the communist movement (or movements, as one must now write) claims to be the legitimate heir of Marxist ideology, Marxism continues to exist, in the Western world, as a non-communist ideology. To be sure, most socialist parties have gone far in severing their ties with Marxism. Yet interest in it has increased in certain intellectual circles. Most of this is roundly critical and, especially in its recent intensified form, is a function of the cold war. The variety of points of view from which Marxism, or what is understood to be Marxism, has been criticized cannot be summarized here. But some of the recent interest has been sympathetic. This may have been stimulated by the collaboration of many diverse elements with communists and socialists during and shortly after World War II. In addition, political, economic, racial, and other difficulties that have beset the

Western world since the war have increased many intellectuals' awareness of defects in their social system. For anyone focusing his attention on negative aspects of contemporary social life, Marxism offers considerable attraction, principally because of two elements: one is the message of inevitable doom derived from the analysis of the capitalist economy; the other is the humanist ethic of Marxism—the emphasis on the evil features of a commercial civilization, the romantic anger at institutions and practices that degrade, oppress, or exploit some men, and the sanguine belief in the inherent goodness of mankind, which under favorable circumstances can and will free itself from inhibiting and corrupting institutions. In the last decade or two interest in this humanist philosophy of Marx and in the early writings in which it is expressed has increased rapidly. Finally, there is some increase in the interest social scientists have in Marx as a precursor of contemporary social science: some of his methodological contributions are only now receiving recognition.

MARXIST SOCIOLOGY

Karl Marx introduced into the social sciences of his day a new method of inquiry, new concepts, and a number of bold hypotheses to explain the rise, development, and decline of particular forms

of society; all of which came to exercise, in the later decades of the nineteenth century, a profound and extensive influence upon the writing of history, political science, and sociology. Marx was also a man of action, a revolutionary, whose political creed stood in a complex and uneasy relationship to his scientific investigations, and his followers, the Marxists of various hues, have tended toward one or the other limit of his ideas, to doctrinal exposition, or to the furtherance of a science of society. Marxist sociology has been one of the principal battlefields in this conflict between objective science and political commitment.

Marx's contributions

On the side of scientific method, Marx made two important contributions. One was to adopt, and to maintain consistently in his work, a view of human societies as wholes or systems in which social groups, institutions, beliefs, and doctrines are interrelated and have to be studied in their interrelations rather than treated in isolation, as in the conventional separate histories of politics, law, religion, or thought. The second contribution was the view of societies as inherently mutable systems, in which changes are produced largely by internal contradictions and conflicts, and the assumption that such changes, if observed in a large number of instances, will show a sufficient degree of regularity to allow the formulation of general statements about their causes and consequences.

Historical materialism. Marx's ideas, which played an essential part in the formation of modern sociology, had been adumbrated in the works of earlier thinkers as diverse in other respects as Hegel, Saint-Simon, and Adam Ferguson, all of whom greatly influenced Marx; and they resemble in some aspects the ideas which Comte and Spencer propounded in their attempts to lay the foundations of sociology. But Marx elaborated his conception of the nature of society, and of the appropriate means to study it, in a more precise, and above all more empirical, fashion than did his predecessors. He introduced an entirely new element by attributing to the characteristics of the economic system and to the derived relations between social classes a predominant influence in determining the structure of each society. It was this feature of Marx's method, to be known subsequently by the somewhat misleading term "historical materialism," which was widely accepted by later sociologists as offering a more promising starting point for exact and realistic investigations of the causes of social change than could be found in such notions as the three stages of man's intel-

lectual development (Comte) or the process of superorganic evolution (Spencer).

Social class and social conflict. Marx's theories followed to a great extent from the above methodological conceptions, which he referred to as the "guiding thread" in his studies (1859, preface). The significance of the economic system of society was elaborated in a theory which traced the formation of the principal social groups—the classes—to the forms of ownership of the means of production and the forms of labor of nonowners. The idea of social change resulting from internal conflicts was developed in a theory of class struggles which made social classes the principal, if not the sole, agents of political activity; and this conception in turn led to the distinction between ruling and oppressed classes and to a distinctive theory of the state. The conviction that social changes display a regular pattern led Marx to construct, in broad outline, a historical sequence of the main types of society, proceeding from the simple, undifferentiated society of "primitive communism" to the complex class society of modern capitalism; and he sketched an explanation of the great historical transformations which demolished old forms of society and created new ones in terms of economic changes which he regarded as general and constant in their operation.

Although this theoretical scheme was intended to have a universal character, Marx actually employed it in a partial manner. His own researches were limited almost entirely to the nineteenth-century capitalist societies, and he gave only fragmentary accounts of the other types of society, in brief allusions in *Capital*, in newspaper articles and correspondence, and in manuscripts which were published after his death (see especially 1857–1858). Furthermore, some of his most important theoretical ideas were derived immediately from the observation of modern societies, and they fit closely only these particular societies. His theory of social classes applies in the main to the formation and development of the modern bourgeoisie and proletariat; it is not so helpful when applied to the phenomena of a caste system. Clearly, the theory of social conflict originated in an interpretation of the French Revolution, the materials for which had been prepared by earlier historians, and it was developed further by observation of the class struggles which accompanied the growth of the labor movement in western Europe.

The concept of ideology, similarly, originated in Marx's criticism of some contemporary social doctrines—utilitarianism, the "critical philosophy" of the Young Hegelians, political economy in some

of its aspects—which he regarded as concealing or distorting the real relationships between men and the actual social conflicts in the European societies of his time (Marx & Engels 1845–1846). It is not a concept which Marx brought, or tried to bring, within the framework of a general sociological theory of knowledge. This intense preoccupation with the origins and development of industrial capitalism is, indeed, a feature of Marx's theories which helps to account for the interest which they still excite. It has enabled Marxists to represent his thought as a modern philosophy that is closely linked with the progress of science and industry, and it has enabled sociologists to discover in it the elements of a theory of industrialization and economic growth.

Marx's influence in the nineteenth century

Marx's scientific writings were not widely noticed or criticized during his lifetime, and he became known principally as the author of a political doctrine expounded in the *Communist Manifesto* in 1848 and as one of the animators of the International Working Men's Association. Furthermore, the early exponents of his ideas, other than Friedrich Engels, were themselves political leaders of the growing working class movement in Europe—men such as August Bebel, Karl Kautsky, and Eduard Bernstein in Germany; Jules Guesde and Paul Lafargue in France—rather than scholars.

Only in the late 1880s did Marx's theories begin to claim the serious attention of academic social scientists. The first major work of sociology to recognize his importance and to display the influence of his thought was Ferdinand Tönnies' *Community and Society* (1887). In this book Tönnies expounded his distinction between two forms of society—"community" (*Gemeinschaft*) and "association" (*Gesellschaft*)—which has become one of the classic themes of sociology. His debt to Marx is indicated by the importance which he assigned to the system of production in determining these different forms of society and by the character of his analysis of modern capitalism. Much later Tönnies published an excellent short study of Marx's life and work (1921), in which he examined more fully the nature and limitations of Marx's contribution to sociology.

A more general recognition by the German academic world of Marx's importance as a sociological thinker became apparent in the 1890s with the publication of a long essay by Werner Sombart on Marx's theory of modern capitalism, books by Rudolf Stammler and Thomas G. Masaryk on the methodological foundations of his theories, and

numerous discussions in scholarly journals. At this time Marx's work also began to be discussed by eminent scholars in other European countries: in Italy by Antonio Labriola (1895–1896), Benedetto Croce (in several essays which are collected in Croce 1900), Giovanni Gentile, and Vilfredo Pareto; and in France by Georges Sorel, who expounded Marx's theories in a number of articles from 1894 onward and published in his journal, *Le devenir social*, some notable essays on Marx by European scholars as well as his own reviews, from a Marxist standpoint, of the work of contemporary sociologists. Marx's sociology also figured prominently in the contributions to the first international congress of sociology held in 1894.

Divergence of Marxism and sociology

By the beginning of the twentieth century, therefore, Marx had been generally accepted as the author of a profound and original system of sociology, yet in the following period the influence of Marxism upon sociology diminished rather than increased. Many of the writers who had first drawn attention to the importance of Marx's theories—among them Croce, Sorel, and Pareto—now became severe critics of Marxist thought and advanced new social and historical theories which, however much they might owe to the initial shock which Marx's ideas had produced, were conceived in an entirely different fashion. On the other hand, a number of influential Marxist thinkers came to regard more critically the claims of sociology as a positive science and to insist more strongly upon the character of Marxism as a revolutionary social philosophy.

In the early 1900s only the small but distinguished group of thinkers who became known later as the Austro-Marxists were engaged in an attempt to set forth and develop the sociological elements in Marx's thought. Max Adler (1925), a philosopher deeply influenced by Neo-Kantianism, represented Marx as having established the epistemological foundations of social science, as Kant had done for the natural sciences; he saw in Marxism a sociological system of causal explanation. Another member of the group, Karl Renner (1904), produced what is still the outstanding Marxist contribution to the sociology of law, a study of the effect of economic forces and social changes upon the working of modern legal institutions. The writings of the Austro-Marxists, however, did not arrest the growing divergence between Marxism and sociology, which appears most clearly in the contrast between the work of Max Weber and Pareto in sociology and the fresh expositions of

Marxist thought by Karl Korsch and György Lukács.

Sociology—Weber and Pareto. Marxism was unquestionably one of the strongest influences upon the work of Max Weber, much of which is devoted either to testing, in a particular context, some part of Marx's theories, or to reassessing in a more general way his concepts and methods. In the first of these directions, Weber's best-known study is that on the origins of modern capitalism (1904–1905), which is intended to show that a body of religious ideas (the Protestant ethic) played a vital part in the development of European capitalism, alongside the economic changes and the rise of a new class, through the inculcation of new attitudes toward wealth, science, and work. From this first revision of Marx's economic interpretation of history, Weber went on to examine on a wider scale the social influence of religious ideas, to amend and supplement the Marxist theory of classes, to outline a radically different theory of political power, and to suggest an interpretation of modern European history as a movement, not toward socialism but, rather, toward greater bureaucratic regulation.

In the sphere of methodology, Weber's preoccupation with historical materialism is evident in his discussion (1907) of a book by Stammmler and especially in an editorial in the *Archiv für Sozialwissenschaft und Sozialpolitik* in 1904, in which he observed that while the materialist conception of history should be rejected as a comprehensive *Weltanschauung*, the interpretation of historical events from the aspect of their economic conditioning or relevance may be accepted as a useful methodological principle, above all in the study of modern societies.

The impression made by Marxist ideas is equally clear in the earlier writings of Pareto, who singled out, as Marx's chief contribution to sociology, the theory of class conflict (1902–1903). This provided the basis for Pareto's own later elaboration of the idea of the struggle between elites for political power, which became the vital element in an interpretation of history directly opposed to that of Marx. Pareto replaced the idea of the progressive development of class systems by a cyclical theory of the rise and fall of elites, and concentrated attention upon the conditions of social equilibrium rather than the causes of social change.

Marxist philosophy. Both Weber and Pareto aspired, though in different ways and with varying success, to establish sociology as an objective social science. Korsch and Lukács, on the other hand, questioned the possibility, and also the value, of

such an objective science, and they expounded Marxism as a philosophy of society which approaches every problem from the point of view of the working class.

Korsch, in *Marxismus und Philosophie* (1923), began by criticizing those thinkers who had regarded Marxism either as a set of methodological rules or as a system of universal causal laws, that is, as a general sociology in the positivist sense. According to him, Marxism includes both empirical and philosophical elements, but the latter are those which distinguish it clearly from other social theories. It is empirical in the sense that it deals with real social movements in modern society and is not in flagrant contradiction with actual events; it is philosophical in the sense that it interprets the facts by means of a conception of history as a process which will terminate in a "classless society." Because of this vision of the future which it contains, it is above all a theory of social revolution which expresses the outlook, and reflects the practical social activity, of a revolutionary class.

In similar fashion Lukács argued, in several of the essays collected in *Geschichte und Klassenbewusstsein* (1919-1922), that Marxism is not to be regarded as an objective interpretation of man's social history—still less as a scientific theory of social evolution—but as an interpretation, from the standpoint of the revolutionary working class, of the historical origins and development of capitalist society. Both writers insisted upon the opposition between Marxism and sociology. For them, Marxism is essentially a theory of history concerned with unique sequences of events and taking account both of objective conditions and of subjective human strivings. Sociology, on the other hand, by its ambition to establish general social laws, in the first place turns man into an object and discounts the subjective aspects of human action and, second, substitutes for the view of society as a historical process the conception of an unvarying system of social relationships which is to be discovered in every form of society.

This idea of Marxism did not find favor with the orthodox Marxist-Leninists, whose opinions were authoritatively expressed at that time through the Third Communist International. However, there were few scholars among the orthodox who attempted to set out an alternative version or to meet the sociological criticisms of Marxism on their own ground. The most important of them was undoubtedly Nikolai Bukharin, whose exposition of historical materialism (1921) is noteworthy for the serious attention which it gives to the difficulties arising from the claim that Marxism is at the same

time an objective social science and the doctrine of a particular social class, and for its discussions of some of the more important criticisms of Marx.

During the early 1900s, the intellectual and political influence of Marxism and the discussions of Marx's sociological theories were largely confined to the continental European countries. In Britain, Marxism made little impact upon sociology, either then or later. The influence of Marxism was greater in the early development of American sociology, but it was soon overshadowed. Thorstein Veblen is the most notable of those who turned to Marx as a source of powerful and radical ideas, which he then developed in his own fashion in theories of the influence of technology upon social structure (1899) and of the rise to power of the engineers (1921). Albion W. Small, who assigned to Marx a place as the Galileo of the social sciences, also played a large part in introducing Marxist ideas and was himself strongly influenced by Marx in working out his theories of social conflict.

Marxist influence since the 1930s

In the period from the early 1930s to the present day, the lines of thought distinguished above have continued and have been enriched by new studies. A number of Marxist writers have upheld the opposition between Marxism and sociology, and they have found new evidence for their views in Marx's early manuscripts, which began to be published in 1932. Thus, Korsch expounded his ideas more fully, but in the same form, in a study of Marx (1938) that was contributed to a series on the great sociologists. A few years later Herbert Marcuse (1941), in a study of the relations between Marx and Hegel, represented Marx's thought as the culminating achievement of the Hegelian dialectical method, as a "critical philosophy" of society which Marcuse contrasted with the positive philosophy and sociology of Comte. The same general view of the nature of Marx's thought, inspired in this case by Lukács, is to be found in the work of Lucien Goldmann on the methods of the social sciences (1959) and on the social context and the literary expression of Jansenism in France (1955); and it has recently been expounded at length by Jean-Paul Sartre (1960), who argued that sociology, as an empirical discipline, either stands opposed to, or must be comprehended within, Marxism, which alone makes possible an understanding of the historically changing totality of social life.

Mainstream of sociology. In the mainstream of sociological thought, many writers continued to turn to Marx's work as a source of specific ideas and problems which they could develop along new

lines. One of the most important ideas which was thus reassessed was that of ideology. It had already attracted the attention of Marxist writers at the end of the nineteenth century, and Franz Mehring's *Die Lessing-Legende* (1893) is the first major attempt to make use of Marx's theories in the interpretation of literary styles. But it was not until a quarter of a century later that Marxist literary criticism revealed its full scope in the work of Lukács, beginning with the publication of *Die Theorie des Romans* (1920) and continuing with his studies of nineteenth-century European realism (1935–1939) and of the historical novel (1947).

Another Marxist writer who was greatly preoccupied with problems of ideology in a broader sense is Antonio Gramsci, much of whose work was done during his imprisonment by the Italian fascist government and has become generally known and influential only since the 1950s. Gramsci was especially concerned with the nature of the cultural dominance exercised by a ruling class, to which he attributed much greater importance than other Marxists had done, and, on the other hand, with the means by which the working class in a capitalist society might resist bourgeois cultural influences while developing its own forms of expression in literature, art, and thought. The notion of "social hegemony" which he introduced was meant to emphasize the interdependence of economic, political, and cultural elements in class conflicts; and his studies of the role of intellectuals, of the educational system, and of other aspects of culture (Gramsci 1949), inspired by this idea, were highly original contributions to the discussion of the old Marxist problem of the relations between "base" and "superstructure" in social life.

The notion of ideology also provided the central theme in the work of Karl Mannheim, who envisioned his task as the elaboration of a general sociology of knowledge from Marx's one-sided criticism of bourgeois ideologies, as a means of understanding the ideological and political conflicts of the twentieth century. Mannheim's writings were symptomatic of a deep concern with the problems of ideology which has lasted until the present time and has produced a number of notable works, from the brilliant critical study by Ernst Grünwald (1934) to the historical survey, dealing at length with Marx and Nietzsche, by Hans Barth (1945).

Theories of class structure. Mannheim was exceptional in attributing such overwhelming importance to the problems of ideology, and it is through other concepts—particularly those of class and conflict—that Marx has had his chief influ-

ence upon modern sociology. All the major theories of class structure, from those of Max Weber, Joseph Schumpeter, and Theodor Geiger up to those of the present day, have begun from Marx's formulation of the question and have been more or less strongly influenced in their conclusions by Marx's own results. Among recent writers, few have been prepared to abandon entirely Marx's model of the class system; but most of them have introduced modifications and have questioned Marx's explanations and predictions. Raymond Aron (1950; 1964), C. Wright Mills, and Ralf Dahrendorf (1959) reject, as inconsistent with the evidence, the constant association between economic ownership and political power which is a basic postulate of Marx's theory, and they draw attention in particular to the alternative bases of political power in societies where private ownership of industrial wealth is nonexistent. Marshall (1934–1962), Lockwood (1958), Lockwood and Goldthorpe (1963), and Mills (1951) examine the changing composition of the main social classes during the past century, especially the changes in the position of the middle classes, and show how these changes affect the relations between classes in a manner of which Marx's theory takes no account.

Class conflict. Most recent sociologists have criticized Marx's theory of class conflict, especially that part of it which asserts the inevitability of working-class revolutions in capitalist societies and the eventual cessation of conflict in a society without classes. The critics, such as Dahrendorf (1959) and Aron (1964), argue that the growing differentiation of functions and the increasing separation between the economic, political, and other spheres in the advanced industrial societies have removed the basis for the coalescence of industrial, political, and ideological conflicts in massive class struggles, and that revolutionary movements have in fact disappeared from these societies. At the same time, they assert that some forms of conflict are unavoidable in any large and complex society and that a society without intergroup conflict, such as Marx envisaged, is sociologically impossible. The work of these writers shows, however, the extent to which the Marxist theory of conflict has influenced recent sociology: it has restored to the center of attention the problems of conflicting interests and values and of the strains produced by social change, which had been neglected in those theories, previously in the ascendant, that were chiefly concerned with consensus, integration, and social order.

Communist countries. It might have been anticipated that with the spread of Marxism as a po-

litical creed in eastern Europe and Asia after 1945, there would be some revival of Marxist sociology in the countries concerned. However, so far this has not taken place. The later years of Stalin's rule were not propitious for any kind of sociology, and Soviet Marxism became increasingly occupied with adapting conventional formulas to political circumstances rather than with developing philosophical or sociological arguments; it was even less concerned with encouraging empirical investigations into Soviet society.

Since Stalin's death there has been a resurgence of sociological research in communist countries, but it is not in any obvious respect inspired by Marxist ideas. Much of the research is concerned with problems which are to be found in all industrialized, or rapidly industrializing, societies—technological change, productivity, urban growth, delinquency, education, and leisure—and it is carried out by the same methods that are used elsewhere. Only in a few instances, where there is some significant difference in the institutional setting of the problems, as in studies of the workers' councils in Yugoslavia, does the Marxist theoretical system appear to have any importance in shaping the investigations.

In the sphere of theoretical sociology, the contributions from communist countries have been few, and they have often revealed the difficulty of maintaining the Marxist system intact. A good example may be found in one of the most distinguished of these contributions: the last work published by the Polish sociologist Stanislaw Ossowski (1957), in which a profound reappraisal of Marx's theory of class leads to conclusions which do not differ widely from those reached by sociologists elsewhere. Ossowski recognizes that substantial changes have occurred in the class structure of capitalist countries, and he observes, in particular, that in all the modern industrial societies the political authorities increasingly determine the system of social stratification, rather than being determined by it, as a rigorous Marxist view would maintain. He also considers and criticizes the arguments which have been put forward, on opposite sides, for regarding both the United States and the Soviet Union as "classless societies." Perhaps his most important contribution, however, is to distinguish the various conceptions of class which were incorporated into Marx's theory, to establish the tentative character of Marx's synthesis, and to show its potentialities for further development so long as it is not accepted as dogma. Ossowski's book may be seen, to some extent, as the harbinger of a more creative period of Marxist thought in communist countries.

Defining Marxist sociology

The record of the encounter between Marxism and sociology since the 1880s shows plainly that while they are distinct, and even opposed, they have never ceased to have a powerful influence upon each other. Marxism is more than a system of sociology; it is a philosophy of man and society, as well as a political doctrine. Sociology, as it has mainly developed in the present century, is an attempt to describe impartially, to measure exactly, and to connect by means of scientific generalizations the diverse phenomena of social life. Even if it be held that a "philosophical anthropology" underlies every major system of theoretical sociology, as Karl Löwith does in his illuminating comparison of Weber and Marx (1932), Marxism still retains a distinctive character; no other body of social thought has become, in this way, the unique doctrine of a political movement and finally the orthodoxy of a ruling party. No other theory, therefore, has been so liable to end in dogmatic assertion and estrangement from social science.

Between Marxism and sociology, the place of Marxist sociology is variable and uncertain. In one sense, Marxist sociology could be regarded as the sociology of those thinkers (for example, Nikolai Bukharin and Max Adler) who, on other grounds, are Marxist in their general philosophical or political outlook. It would then be of the same kind as any other school of sociology—let us say Thomist or Hindu sociology—which is based directly upon a philosophical world view. But it would still be affected by, and would have to respond to, the findings of empirical social research; and at some stage Marxists would be led to consider, as has happened in recent years, whether in fact there can be a separate Marxist sociology any more than there can be a separate Marxist physics.

In a broader sense, however, Marxist sociology might be regarded as including the work of all those thinkers who attach prime importance, in the investigation and explanation of social events, to the role of economic interests, relations between classes, and intergroup conflicts, without necessarily agreeing with the particular conclusions that Marx himself reached. But this category may seem too broad, since it would include those, from Weber and Pareto up to the recent sociologists discussed above, who have acknowledged Marx's outstanding importance as a thinker and have turned to his work for concepts and hypotheses, but who have revised or rejected so much of his system that it would be eccentric to refer to them as Marxists.

Lastly, Marxist sociology may be treated as a methodology, as a persistent critique of the aims and methods of the social sciences. In this form it has undoubtedly been prominent and important, as the writings of Lukács, Marcuse, and Sartre bear witness; but here it becomes not so much Marxist sociology as Marxist "anti-sociology."

MASARYK, THOMAS G.

Thomas G. Masaryk (1850-1937), Czechoslovakian statesman and social theorist, was born in Hodonin on the Moravian-Slovakian border. His father, a Slovak, was a coachman on one of the imperial estates; his mother came from a small Moravian town. He studied first at the Gymnasium in Brno, but after a conflict with the Roman Catholic church he left there and attended the Gymnasium in Vienna. Later, at the University of Vienna he wrote his dissertation, "Das Wesen der Seele bei Plato" (1876), under the philosopher Franz Brentano. In 1877 he studied with Gustav Theodor Fechner at the University of Leipzig, but Masaryk

was influenced less by Fechner than by Charlotte Garrigue, a music student whom he met at Leipzig and later married. She came from a well-to-do American Unitarian family, whose religious faith had been shaped by Theodore Parker, and her religious views helped Masaryk define his own. Through her he also gained an understanding of English philosophy and American society: Locke, Hume, Mill, and Spencer influenced his thought, and American institutions guided his social and political aspirations. Masaryk acknowledged the extent of his debt to his wife by taking Garrigue as his middle name.

In 1879 Masaryk became *Privatdozent* of philosophy at the University of Vienna. His interests centered on sociology and on Czech political life. His first important book was *Der Selbstmord als soziale Massenerscheinung der modernen Civilisation* (1881). In this work he attempted to deal with suicide as a social phenomenon and to support his conclusions statistically. According to Masaryk, Europe was then in a period of high suicide rates. This could be directly attributed to a decline of monotheistic religion and thus was the "fruit of progress, of education, of civilization" (p. 146).

When the Czech university was established at Prague in 1882, Masaryk was called there as extraordinary professor of philosophy. He held his post for 32 years. During those years he helped to form the political and moral ideas of a significant part of the Czech and South Slav intelligentsia, although before 1914 he was not popular among the Czechs. His opposition to the Catholic church, on the one hand, and to Marxism, on the other, his pronounced Westernism, and his "realistic" moderation in political and national demands prevented him from exercising a wider influence.

While a professor in Prague, Masaryk published his *Versuch einer konkreten Logik: Klarifikation und Organisation der Wissenschaften* (1885), his last scholarly work. From then on, most of his work was more directly concerned with moral and political education. He founded and edited several journals, among them *Athenaeum* and *Naše doba* ("Our Epoch"), and a political weekly, *Čas* ("Time"). He was active politically as a member of the Austrian Reichsrat, representing first the Young Czech party, from 1891 to 1893, and later, from 1907 to 1914, the tiny Progressive party (more generally known as the Realist party), which he had founded.

Masaryk's political activities reflected the themes of his writings published during these years, in which he discussed Czech nationalism and deplored the deficiencies of the Marxist approach to basic social problems (1895; 1896; 1898). He knew

Russia from both studies and travels and wrote two volumes interpreting Russian culture, history, and religion (1913). He planned but never completed a third volume, on Dostoevski, whom he regarded as the key author for an understanding of Russia and whose philosophy and outlook he totally rejected.

Masaryk's own nationalism revived and extended the ideas underlying the work of the first modern Czech historian, František Palacký. Masaryk saw the Czech national awakening in the nineteenth century as a continuation of the Hussite reformation of the fifteenth. And the movement of the Bohemian Brethren, in his view, encompassed the highest aspirations of the Czech nation and of the whole of mankind. This vague, moral nationalism was sharply criticized by professional Czech historians like Jaroslav Goll and Josef Pekař.

In 1914 Masaryk left Prague, and during World War I he became the leading propagandist urging the establishment of independent small nations (1918) and the identification of Czech national traditions with those of Western democracy. He made London the center of his activities and in 1917-1918 visited Russia and the United States. It was his plan to create a Czechoslovakia in which Czechs and Slovaks would be united on the strength of ethnic principles and Germans and Magyars would be included on the basis of historical principles; his views prevailed at the Versailles peace conference. He was elected the first president of Czechoslovakia in 1918 and was continuously re-elected until he resigned in 1935 for reasons of ill health. Until 1948 he was revered as the "father of his country," but because of his strong anti-Bolshevik stand the post-1948 communist regime has been sharply critical of him.

MASS PHENOMENA

The term "mass phenomena" as it is used in this article is intended to cover the same range of behavior as that denoted by two frequently used similar expressions: "collective behavior" and "mass behavior." Under this general rubric a number of more specific terms have commonly been employed to refer to the five major subtypes of mass phenomena: (1) apathy, (2) panic, (3) mob, (4) craze, and (5) social movement. These major subtypes are in turn divisible into still finer subclassifications, denoted by a miscellany of terms which have come to be used conventionally to describe local varieties of unique forms. Thus some mob situations are commonly labeled "riots," as in "race riots," and certain others are referred to as "lynchings"; some social movements are called "revitalization movements," and these are still further classified by local terms, such as "cargo cults" (Oceania), "nativistic move-

ments" (American Indians), etc. The nomenclature for mass phenomena is so vast and so intricately related to varying criteria that there is no reason to review or attempt to rationalize it in detail here. It should be noted that there are also other terms, like "mass hysteria," which crosscut this natural historian's nomenclature. These terms draw attention to certain psychological or social attributes which several types of mass phenomena have in common and which they sometimes share with behavior that is not included under the category of mass phenomena.

Definition. Although there seems to be an intuitive recognition by most observers that all of these forms of human behavior have something in common which justifies treating them as a unit, the efforts to define this commonality are not always in agreement. Smelser has provided a definition in his book, *Theory of Collective Behavior*: "we define collective behavior as mobilization on the basis of a belief which redefines social action" ([1962] 1963, p. 8). Brown (1954) in his discussion of the varieties of mass phenomena suggests a set of dimensions for their classification (size, frequency and regularity of congregation, frequency and regularity of polarization of attention, and continuity of identification of individuals with the group), but he provides no definition. Any definition must not only state common features of the various referents of the term but must also state common features which nonmembers of the class do not possess. Certainly the term "mass phenomenon" cannot be taken to refer to all attributes of a large group of people (however "large" may be defined); otherwise, we should have to include culture, acculturation, culture change, population growth, voting behavior, rumor circulation, and many other social and cultural attributes and processes under the rubric of mass phenomena. Neither can we comfortably include all situations in which a large group of people is collected in one place, or in which many people are simultaneously the target of communication: not all audience or crowd behavior will fall within the intuitive boundaries of the concept. Nor can we be satisfied with a definition that emphasizes a single psychological or social process—such as fear or mobilization—without regard to the size (or "mass") of the group involved.

If we keep these considerations in mind, it would appear that Smelser's definition is nearly adequate to our needs. But its emphasis on mobilization makes it difficult to include the disaster syndrome (including shock, apathy, disorientation, and the very opposite of mobilization of a

group for action). Thus I suggest the following, somewhat less analytical, definition: "*Mass phenomenon*" signifies that class of social event in which a large number of people at the same time behave in a way which constitutes a notable interruption of their routine, socially sanctioned role behavior.

The varieties of mass phenomena. Let us now consider how the characteristics recognized by the above definition are manifested in the subclasses of mass phenomena to which I have referred.

Apathy and the disaster syndrome. The disaster syndrome occurs after a major catastrophe, usually physical, has destroyed important features of a group's natural and/or cultural environment, frequently with severe casualties. In this case the interruption of routine behavior implies the virtual cessation of any kind of adaptive behavior. Initially, the surviving population appears to be in a state of shock: people are passive, emotionally numb, relatively insensitive to physical pain, apathetic, disoriented, unable to understand the magnitude of the disaster, and unresponsive beyond minimal survival action; little mutual aid is undertaken, and remedial action is often trivial. After minutes or hours—and perhaps longer—as aid enters from outside the disaster area, the survivors become less apathetic and enter into a suggestible stage in which, under leadership, they can begin to engage in rescue, repair, and other useful activities. Eventually the syndrome moves into a euphoric stage of mutual aid in reconstruction, and at last it tapers off into the culturally standardized routine. [See also DISASTERS. For discussion of the disaster syndrome see Wallace 1956a.]

Panic. Panic occurs when a group is subjected to an overwhelming and imminent threat to which escape appears to be the only effective response, and when escape routes are perceived to be inadequate to accommodate all of the group before the impact of the threatened event. In such a situation, the group structure disintegrates into an "every-man-for-himself" state of anarchy: individual escape tactics are apt to be chosen impulsively, with little foresight and with restricted attention to the real environment; jamming is likely to occur at the exits from the situation, with attendant injury, loss of life, and increased slowing of the escape flow. The interruption here is twofold: first, the abandonment of group structure by individuals (even though the group itself may have had a plan for handling the problem by reducing the threat or by orderly escape); and second, the severe constriction of perceptual and cognitive functions of individuals under the stress of fear.

Mob. The mob is an angry group which attacks and attempts to injure or destroy an object (usually a person or persons or some item of material culture identified with some human being or group). It differs from a military or police force insofar as the members of the mob are not performing socially sanctioned roles and insofar as the attack is not undertaken as an implementation of a rational policy concerted by the mob's members (although, to be sure, there may be a leader who, unknown to the rank and file, is exciting and directing the mob, carrying out a policy of his own or of some other group). The interruption of routine behavior here is the abandonment of the socially sanctioned roles of peaceable, law-abiding private citizens and the assumption of primitive judgmental and punitive roles which are carried out with minimal concern for justice (as locally defined) or for long-term consequences.

Craze. The craze is a short-lived rush, by many persons, to worship, to touch, or to acquire some object (human or material) or characteristic of value. In its milder forms it may be referred to as a "fad"—a clothing style, a type of haircut, a dance; in more extreme expression it may be termed a "craze" (proper)—such as the adulation of a popular singer by thousands of screaming fans, a kind of financial investment, or a rush to settle new lands or to exploit unclaimed mineral resources. The interruption here is the abandonment of previous objects of interest and the substitution for them, by many people at the same time, of a standardized object. [See FASHION.]

Social movement. The social movement (or revitalization movement), whether religious or political and whether revolutionary or reformative, is by definition an organized effort to induce the members of a community to abandon certain customs or practices and to adopt different ones. The participants in the movement, starting with the prophet or leader, then his disciples, and eventually at least some followers, do in fact change their ways and the distribution of their energies. In every social movement, therefore, there is an interruption of a routine and the substitution of a new pattern of behavior, rationalized by reference to an ideology. The aim of the movement, of course, may be to accomplish a much more extensive interruption and to institute a much more pervasive new system than ever is accomplished. [See SOCIAL MOVEMENTS.]

Phenomena not considered. It may be pointed out that in the above discussion we have left out certain phenomena which are included in some treatments. Thus, for instance, we have not treated

crowds per se as examples of mass phenomena, because many crowds are engaged in perfectly routine, standardized activities. Thus, for instance, we do not treat as a mass phenomenon the audience at sports events, at theaters, and at religious ceremonials because it is an organized group interacting with another group (the performers) in a patterned, culturally institutionalized way, even in cases (as at political rallies, voodoo rituals, or Holy Roller types of religious revival) where the behavior is excited or hysterical in a technical sense. Similarly, crowds on arteries of transportation, in markets, or in military units, however poorly or well organized, are not treated as mass phenomena, because the behavior involved is perfectly explicable and predictable from a knowledge of the culture. Nor do we consider the gross characteristics and social activities of vast aggregates—like "the masses," "the consumer," "the proletariat," "the Negro," or "the Southern white"—as mass phenomena in themselves.

The reader may, however, note that while the behaviors which have been treated as mass phenomena do have in common the feature of interruption of routine, they range from the nonpurposeful, inactive, maladaptive extreme of the disaster syndrome, through grades of increasingly purposeful, active, adaptive behavior, to the social movement, which is eminently purposeful, active, and adaptive. In the next section we shall take up the question of explanation, not only for the mass phenomenon in general, but for the occurrence of its varieties.

Explanations of mass phenomena. Explanations—and predictions—of mass phenomena usually invoke a mixture of psychological and sociological principles. Sometimes efforts are made to provide purely sociological explanations; these efforts, however, are generally justified by pointing out the deficiencies of early psychological theories that postulated "herd instincts," "the group mind," and the atavistic vulnerabilities of civilized men. Although such appeals to supposed universal psychological tendencies are fruitless as guides for research, the "pure" sociological approach merely reintroduces psychology through the back door via definitions of "social" concepts in terms of sentiments, goals, values, needs, and so forth. It seems wisest to make use explicitly of both psychological and sociological variables, evaluating the utility of each by more or less operational criteria.

On the most generic level, the following conditions seem to be required for the occurrence of any mass phenomenon: (1) a certain type of information must be presented to the members of

the target group, approximately simultaneously; (2) the type of information which is presented must describe a difference between the individual's present situation and that which either has obtained in the past or very probably will obtain in the future; (3) the difference must be sufficient to constitute a dramatic gain, or loss, of important values (such as life, health, or self-respect); (4) the present or future loss must be perceived as avoidable, or the future gain as achievable, if something is done. The resultant action is, in fact, the behavior described as the mass phenomenon.

Further conditions need to be specified before it is possible to predict what that action will be. Important classes of such conditions are, first, the precise nature of the threat, disaster, or future gain; and, second, the existing cultural system of the target group—its goals, its fears, its ontological beliefs, its social organization, and its modal personality structure.

Apathy and the disaster syndrome. In a major disaster or in a situation of threat from which no escape route can at the moment be perceived, the mass action is, in effect, no action, or apathy: the only relief from the awareness of an unchangeable contrast between good past and bad present, or good present and bad future, is denial or withdrawal from awareness of reality as thus defined. The disaster syndrome, the cultural situation of universal demoralized individual behavior resulting from anomie, and the fictional social condition of an impending world's end described in Nevil Shute's popular novel *On the Beach* are examples of the apathetic response. It is worth noting that panic does not occur under these conditions.

Panic. Where the catastrophe has not yet occurred and there is still a possibility—but a narrow and diminishing one—of escape, panic occurs instead of apathy. The action involved is frequently precipitate physical flight, but other activities may represent the appropriate mode of escape: the selling of property, as in a financial crash or in a neighborhood threatened with invasion by an unwanted social group; or the hoarding of food in anticipation of shortages.

Mob. Where a catastrophe may occur but is not imminent, and where its likelihood is believed to be increased by the actions or inaction of some other person or group who is not believed to be responsive to the fears of the threatened group, a likely response is mob action. Mob action is also likely where an important goal is believed to be achievable but blocked by the action or inaction of some nonresponsive social group. The critical factor here seems to be the group's belief that the

disparity between present and future (whichever way the balance lies—good present and bad future or bad present and good future) can be resolved only if some weak and evil persons are injured or destroyed. In the mob situation, furthermore, it is possible for the group to find relief for their feelings of guilt in scapegoating, that is, attributing to others those faults, often irrelevant to the precipitating issue, whose recognition in themselves would cause the members of the mob to feel further discomfort. [See PREJUDICE.]

Craze. In the craze, the members of the group seem to be driven by both a hope for some desirable thing and a fear of being left behind while others enjoy themselves. In a sense the craze is a "positive" panic: the urgency of the situation lies not in the imminence of danger, escape from which becomes less likely with each passing moment, but in the availability of a benefit, access to which may be reduced in the near future.

Social movement. The social (or revitalization) movement is the most positive, most organized, and most deliberate of the mass phenomena. In polar contrast to apathy, the participants in such a movement must maintain an effective social organization over considerable periods of time. The social movement defines the present as a transfer point between an undesirable past and a glorious future. It mounts a carefully calculated campaign, by a mixture of religious and political procedures, to transform society from an evil to a good condition. In the social movement, the character of the existing culture is closely relevant to what happens. Prevailing beliefs about the mechanisms of change are apt to determine the form of—but not to precipitate—the movement. Thus, among Jews the belief in a Messiah, and among Muslims the belief in the Mahdi, have heavily colored the movements that have occurred among these peoples; the Melanesian "myth dream" of their ancestors returning with cargo and the Christian concept of the millennium have shaped many of the movements in their respective parts of the world. [See MILLENARISM; NATIVISM AND REVIVALISM.]

It should finally be pointed out that mass phenomena of different types can follow one another in sequence in a given group. Thus, an apathetic phase following the awareness of disaster may be succeeded by a revitalization movement; a rioting mob may be swept by panic; an enthusiastic meeting of participants in a craze may turn into a riot if the object of the craze is withheld; and so on. It follows from the definition and from the general statement of conditions that a mass phe-

nomenon, once established, can readily be transmuted in form as the nature of the information given to the group is varied.

BIBLIOGRAPHY

The bibliography on mass phenomena is extensive and diffuse. Smelser 1962 contains the most useful general bibliography on the topics considered in this article, except for the subject of apathy, which is not treated. The National Academy of Sciences-National Research Council has published a series of monographs on disaster behavior, including the apathetic reaction, and maintains a large card catalogue of works on disaster. See also the bibliographies of COLLECTIVE BEHAVIOR and DISASTERS.

MASS SOCIETY

"Mass society" is best understood as a term denoting a model of certain kinds of relationships that may come to dominate a society or part of a society. Terms like "mass production" and "mass communication" refer to activities that are intended to affect very large numbers of people who are seen, for these purposes, as more or less undifferentiated units of an aggregate or "mass." Similarly, a "mass society" is one in which many or most of the major institutions are organized to deal with people in the aggregate and in which similarities between the attitudes and behavior of individuals tend to be viewed as more important than differences. Societies or institutions organized in this way are said to have a "mass character," and the life of individuals in such societies is said to be governed primarily by "mass relations."

The structure of mass society

Large populations do not by themselves produce mass relations, although mass relations are less

likely among small populations. In the past, large societies were divided into many segments with relatively clear boundaries separating each segment from the other. Even though a society contained thousands of villages, all of them much alike, it was not a mass society because human relations centered on the village and supported the integrity of the village as a social unit.

Unlike the village-based society, the mass society does not help to sustain spontaneously evolving and durable social units. "Mass" in its simplest sense means an aggregate of people without distinction of groups or individuals. In mass production, for example, workers are organized according to the logic of specialization and control rather than as members of social groups or as distinct persons, and production is geared to a market of similarly undifferentiated people. Mass production, of course, involves a highly structured mass, by virtue of the division of labor and administrative organization, and it is therefore to be distinguished from the unstructured mass represented, for example, by the aggregate of unemployed workers. Moreover, some industries have more of a mass character than others: the assembly-line system of automobile factories is much more conducive to the emergence of the mass than is the craft-based system of printing (Blauner 1964). Nevertheless, the mass character of the market is a decisive factor in the organization of most manufacturing industries.

It is not so much the large size of the population as it is the large scale of activities that favors mass relations. Where the scale of activity is very great, it is more likely that the social relations which individuals bring with them or develop will be easily ignored or transformed by the dictates of technical efficiency or effective control. Thus, mass relations are likely to emerge where large-scale activities predominate, as in nationwide organizations, markets, audiences, and electorates.

The decline of community. Large-scale activities favor the emergence of the mass because they tend to develop at the expense of communal relations. The local community comes to provide for fewer of its members' needs and therefore cannot maintain their allegiance. The rural community no longer is isolated and self-sufficient. As it becomes dependent on the city, and particularly on national markets and organizations, the rural community loses its significance and cohesion. The city does not develop the communal life that was formerly provided by the rural community. The individual who migrates to the city does not enter the community as a whole, nor is he likely to enter a subcommunity of the city. The urban subcommunity loses its coherence as a result of the increasing

scale and specialization of common activities. Instead of affiliation with a community, the urban resident frequently experiences considerable social isolation and personal anonymity.

Ethnic and religious groups also tend to lose their coherence as their members are drawn into large-scale organizations and arenas. Individuals derive less of their social identity, style of life, and social values from their ethnic and religious background. As ethnic cultures come in contact with mass culture, they cease to preserve their unique qualities. Religious groups tend to de-emphasize their theological and liturgical differences. The particular religious affiliation loses its significance for both religious and secular beliefs and conduct. Even if people continue to associate primarily with coreligionists, this has little influence on the quality of their lives or on the manner of their participation in the larger society.

Like local, ethnic, and religious communities, class-based communities tend to lose their importance and coherence where the whole population is incorporated into large-scale activities. Social classes weaken as sources of distinctive values, styles of life, and social identity; and they increasingly resemble one another in the beliefs, values, and interests of their members. Class distinctions are leveled, and class boundaries are blurred. Class consciousness and class solidarity dissolve into mass consciousness and mass solidarity. The lower classes are increasingly brought into arenas of communication, politics, and consumption previously limited to the higher classes. Class differences in opportunities and modes of participation that remain are no longer believed to be desirable or permanent. Common symbols of the good life and of rights and obligations replace class-differentiated concepts. Classes remain as categories of people who differentially share in common ways of life rather than as self-conscious groups with distinctive ways of life. Status strivings and anxieties abound, but this testifies to the ambiguity of status where fixed social hierarchies no longer exist.

The ascendancy of organization. Mass organizations replace communal groups as the characteristic units of society. Mass organizations are large and formal, but some large and formal organizations exhibit more of a mass character than do others. The additional features that constitute a mass character include a membership that is structured primarily by administrative devices rather than through social relations, and, correlatively, activity that is mobilized from the center rather than generated through various groups within the organization (Selznick 1952). Mass organizations do not build on the primary relations of members,

nor do they support and facilitate primary relations among members. The result is a relatively unmediated and depersonalized relationship between the membership and the organization. Where the organization seeks a highly active membership, as in certain kinds of mass parties, intense identifications with the organization may be created. Most mass organizations do not seek a mobilized membership, however, and do not possess the symbols or other resources for mobilization. Instead, they are content with passive support from their members, who in turn acquire little social identity from the organization. Solidarity tends to be weak under these conditions, and symbolic or personal gratifications correspondingly slight. Unlike membership in communities, membership in mass organizations tends to be a fragile bond because relations are impersonal and leveled. This weakness is indicated by high rates of mobility of members, as they respond to opportunities for greater benefits and to new interests elsewhere.

As mass organizations replace communities, so do "mass arenas" displace local arenas. Mass arenas, including national markets and electorates, are spheres of activity common to all sections of the population. Like mass organizations, mass arenas are managed from the center rather than structured through social relations. They are managed primarily through the mass media of communication, since only in this way can an entire population be presented simultaneously with the same objects of attention. People participate in mass arenas by selecting from among the alternatives presented through the mass media. Since the alternatives are standardized in order to reach the entire population simultaneously and since they are directed to individuals as undifferentiated members of the society, participation transcends the individual's social relations (Blumer 1939).

Mass equalitarianism. Pervading all kinds of mass relations is a common normative orientation of equalitarianism. All members of mass society are equally valued as voters, buyers, and spectators. Numerical superiority therefore tends to be the decisive criterion of success. In the political realm this means the number of votes; in the economic realm it is the number of sales; and in the cultural realm it is the size of the audience. Mass equalitarianism is strengthened by the attenuation of the social bases of inequality, notably membership in ethnic and religious groups and especially in social classes. In contrast to the equalitarianism of small numbers, as in friendships, mass equalitarianism emphasizes the similarities of individuals rather than the uniqueness of persons.

Mass equalitarianism is also linked to the bu-

reaucratization of organization. Mass organization simultaneously encourages the bureaucratic centralization of governing powers and the leveling of social differences among the governed (Weber 1906-1924). The incorporation of all sections of the population into large-scale activities summons centralized organization for coordination and control. Mass bureaucracies favor the leveling of social differences in the interest of efficiency. By treating everyone alike, according to functionally rational rules and procedures, mass bureaucracies foster equalitarianism. However, bureaucratic recruitment on the basis of professional competence raises new hierarchies. To be sure, careers open to talent are in greater harmony with equalitarian beliefs than is selection according to family and property. But professional elites are nevertheless elites and thereby introduce new social distinctions. This is a source of strain in modern society; in the political realm, for example, there is a tension between planning by experts and participation by mass electorates [see ELITES].

Mass equalitarianism is expressed in the populist character of mass society. Whatever is believed to express the popular will or to meet the most widely shared expectations is considered legitimate (Shils 1956). Political regimes strive to be popular regimes, whether they are dictatorial or constitutional. While this popular legitimation of authority centers in the polity, it pervades all kinds of social institutions. Populism places a premium on the capacity of leaders to create and placate popular opinion. Those who are effective in mobilizing large numbers of people have great power, and this generally means the leaders of mass parties. The mass leader seeks to embody and reflect popular desires; masses, not elites, are the ultimate sources of legitimation in mass society. This leads elites to make themselves readily accessible to popular pressures: that is, they are forced to be responsive not only to periodic expressions of public opinion through regular channels such as elections, but also to momentary and *ad hoc* representations of whatever is claimed to be popular.

Leaders, of course, do not seek merely to respond to mass opinion. They also try to control it. Since they lack firm bases of independent authority, their control tends to take the form of manipulation and mobilization rather than command. The very presence of large numbers of only loosely organized and committed people summons efforts of leaders to manipulate and mobilize them. For if elites are highly accessible to mass pressures, so are masses readily available for mobilization by elites. People are receptive to direct appeals from remote elites, because they are poorly attached to proximate sym-

bols and relationships and increasingly caught up in distant events and activities (Kornhauser 1959).

Mass movements. As mass society develops, there is a growing cleavage between those who continue to be integrated in local groups and those who have already been incorporated into mass relations. In part this is a difference between the old classes and the new classes—craftsmen versus industrial workers, independent entrepreneurs versus industrial managers, free professionals versus members of professional staffs, and so forth. Increasingly isolated from the larger society, members of the declining classes readily come to believe that they are the victims of it. More generally, the locally attached, in their resentment of the ascendancy of big cities, big government, big business, and big labor, become receptive to the appeals of mass movements directed against the forces of mass society.

Then there is the growing number of people who have been detached from communal relations but who are not, or not yet, incorporated into mass relations. It is likely to include, among others, new migrants to the cities, new workers in the factories, and, generally, the younger and newly mobile members of the society. In the absence of strong group ties, they are less constrained and more restless than those who continue to be rooted in communal groups or those who have been fully incorporated into mass relations. These poorly attached and unintegrated people are readily available for activist modes of intervention in political life and for participation in mass movements that promise them full membership in the national society.

Thus, modern mass movements are characteristically composed of people who either seek entry into mass society or seek to reverse the processes of mass society. Like mass organizations, mass movements do not build on existing social relations but instead construct direct ties between participants and leaders. When a mass society has successfully incorporated most sections of the population into its central institutions, mass movements may become less widespread. In a highly developed mass society, mass participation is institutionalized in the form of mass organizations, especially mass parties, but also mass unions and similar associations, universal suffrage, extensive publicity of political men and events, and the official symbolism of popular government [see SOCIAL MOVEMENTS].

Criticism of mass society

Early critics. The concept of mass society had its major intellectual origin in the nineteenth-

century criticism of the revolutionary changes in European (and especially French) society. Many thinkers believed that the decisive social tendency was the change from aristocratic to democratic society. It was not simply that a shift occurred in the class composition of governing groups. More fundamental was the shift that these thinkers perceived in the bases of social order. Formerly, standards of value and conduct had been assumed to exist as part of a natural order of society; in democratic society, by contrast, the arbitrary will and opinion of the masses were replacing established standards.

Early representatives of this kind of social criticism of the democratization of society were Catholic thinkers like Joseph de Maistre and the vicomte de Bonald. Following the ascendancy of portions of the middle classes, marked by such events as the accession in 1830 of Louis Philippe, the bourgeois king, in France and the passage of the 1832 Reform Act in England, liberal thinkers adopted mass society ideas, not to defend the old order but to assess the strengths and weaknesses of the new order. Thus, Tocqueville (1835) moved from a fairly hopeful analysis of the possibilities of preserving standards in a democratic society (in light of his examination of America) to a more pessimistic view of the matter following the 1848 revolution in France. Even so influential a liberal thinker as J. S. Mill found himself in wide agreement with Tocqueville's more pessimistic diagnosis of democratic culture. Burckhardt and Nietzsche, among many other late nineteenth-century romantic thinkers, sought to interpret changes in European society as the erosion of culture. Ortega (1930) later formulated a highly popular version of this view.

This aristocratic criticism of the development of nineteenth-century society profoundly influenced democratic criticism of the development of twentieth-century society. Where the first centered on the intellectual defense of elite values against the rise of mass participation, the second developed as a defense of democratic values against the rise of totalitarianism. The defensive posture of the aristocratic thinkers was adopted by democratic thinkers who, having won the nineteenth-century war of ideas and institutions, now sought to preserve their gains against the totalitarian challenge. Thus, such students of totalitarianism as Lederer (1940), Mannheim (1935), Fromm (1941), Neumann (1942), Arendt (1951), and Kornhauser (1959) see in the fragmentation of society the opportunity for new forms of domination based on the mobilization of large populations.

Two kinds of analysis closer to the social sci-

ences have contributed significantly to the development of the idea of mass society during the past century. One is the effort to distinguish between traditional and modern societies, a line of analysis that has become a central theoretical perspective of sociology. An early formulation of this perspective was Maine's distinction between societies dominated by status relations of kinship and those dominated by contract relations of individuals. Tönnies (1887), in his highly influential analysis of *Gemeinschaft* and *Gesellschaft*, elaborated Maine's thesis. Further evolution of this line of analysis is to be found in Durkheim's theory of social solidarity and anomie (1893; 1897) and in Max Weber's treatment of traditional and bureaucratic authority (Weber 1906-1924). What made this kind of sociological theory relevant to the idea of mass society was its analysis of the atomization and depersonalization of social organization resulting from modernization. This became a central thesis of urban sociology, as in the writings of Simmel (1902-1903), Park (1916-1939), and Wirth (1933-1953). [See COMMUNITY-SOCIETY CONTINUA.]

The development of mass psychology provided still another source of ideas about mass society (Reiswald 1949). Gustave Le Bon, Scipio Sighele, and Gabriel Tarde were leading students of mass behavior at the turn of the century. In their analysis of the heightened suggestibility and manipulability of people no longer constrained by communal ties and traditional authorities, these theorists contributed to the social psychology of mass society. This line of analysis was given a more sociological and less polemical cast by American students of what came to be called "collective behavior" (Blumer 1939) [see COLLECTIVE BEHAVIOR]. Many of these themes from sociology and social psychology were drawn together in Mannheim's critical analysis (1935) of the effects of the "fundamental democratization" and "growing interdependence" of society.

A common perspective unites these theories and makes them part of the history of the idea of mass society. It is a view of modern society as containing certain fundamental pathological tendencies, which are believed to inhere in its development. The theory of mass society adds to such concepts as "democratic society," "urban society," and "industrial society" an emphasis on the socially disintegrative effects of democratization, urbanization, and industrialization. Foremost among these effects are the decline of community and authority and the spread of pseudo-community and pseudo-authority.

Pseudo-community. During the 1920s and 1930s, a number of American sociologists reported on

various aspects of modern life and generally stressed the anonymity and atomization of persons in contemporary society. Following World War II, this portrait of modern life was subject to considerable criticism on the grounds that primary relations are much in evidence in the factory, the army, and other allegedly impersonal organizations. Kinship networks, neighborhood bonds, and local activity were observed in a number of urban and suburban settings, and primary-group mediation of mass communications was shown to prevail over completely atomized audiences. Such observations suggest that the decline of community is at most relative to the condition of premodern society (Greer 1958).

There is much more to the problem of community than the question of the mere presence or absence of personal attachments and communal bonds. Students of mass society assert that the functions of primary groups are weakened under conditions of modern society, not that primary groups are absent. The decreasing role of primary relations in the social organization of mass society and their increasing *isolation* from the larger society weaken them as sources of meaning and support for the individual in the larger society. Moreover, they are more easily broken because they receive less support from the institutional framework of society. Both weaknesses stem from the attenuation of the *links* between primary relations and the major functional areas of society.

The isolation of primary relations creates the need for more inclusive bonds of solidarity and gives rise to a search for new forms of community. The barriers to community thrown up by the mass character of society heighten receptivity to the appeals of pseudo-community. This hypothesis has been applied to otherwise widely diverse social contexts. The German middle-class youth movement at the beginning of the century made the "return to *Gemeinschaft*" its cardinal article of faith. The Nazi movement subsequently inscribed the "folk community" on its ideological banner and won many adherents on the strength of this appeal. The totalitarian mass movement is only the most dramatic and extreme case of pseudo-community. Much more mundane cases have been examined in the context of American life. For example, campaigns of mass persuasion exploit themes of community and personalization (Merton 1946), and programs of "human relations" in industry exploit unfulfilled needs for social bonds and participation in the interest of greater worker efficiency (Mayo 1933). These ideologies and programs simulate but do not create community, and consequently they

make people more available for manipulation and mobilization. They exploit a general dilemma facing the individual in mass society: either he demands highly personalized meaning from the mass enterprise and suffers frustration, or he withholds commitment to it and suffers loss of identity.

"Social alienation," "false personalization," "enforced privatization," and similar notions found in the writings on mass society point, however unsteadily, to the pathology of community in modern society (Nisbet 1953; Riesman 1950). This concern with the *quality* of social relations—the fabrication of symbols and relations, the exploitation of unfulfilled needs for personal response, and related matters—marks the perspective of mass analysis. As a perspective, it invites attention to the various distorted forms and expressions of the search for community, to the social conditions that promote them, and to the consequences for individuals and institutions that flow from them.

Pseudo-authority. The decline of authority accompanies the decline of community. For the loosening of the various cohesive groupings that make up a society is at the same time the dissolution of the authority of these groups over the individual. Traditional standards and customary authorities anchored in kinship, church, and community are replaced by bureaucratic systems of legal and political control. The rationalization of authority liberates the individual from the often harsh and always close constraints of the cohesive group; however, it also removes the direction and support supplied by such a group but not by the large and impersonal bureaucracy.

Many students of such relatively democratic political societies as those of England and the United States have been quick to criticize this conception of the bureaucratic society on the grounds that it fails to see the pluralist character of these societies, especially the dispersion of power and authority among diverse and independent social groups. Thus, interest-group activity and influence are found to be extensive on all levels of government; power and authority in many local communities are observed to be widely distributed among competing groups; and party loyalties are reported to possess considerable stability. Such findings appear to contradict notions of contemporary society as a condition of social and political atomization (Bell 1960).

Mass theorists question, however, whether these observations in fact confirm a continuing vitality of social pluralism, or whether the pluralist group structure is not itself subject to the forces of mass society. Social pluralism undoubtedly receives a

certain impetus from the elaborate functional differentiation of the large-scale industrial society: the proliferation of specialized occupational groups is the principal case in point. But since these associations are specialized, tend to be nationwide, and often do not incorporate the work group or other social relations of the individual, they are transformed into mass organizations (Nisbet 1953; Selznick 1952).

Moreover, the interests underlying the formation of diverse organizations tend to be creatures of a complex and specialized economy that splits the person from the role, so that they possess only a limited capacity to elicit broad or deep personal commitment. If the interests are not very substantial and distinct, the organized representation of interests that constitutes a pluralist system will be correspondingly insubstantial and amorphous. The affluent society and welfare state also reduce the urgency of these interests. New sources of disaffection appear in the mass society, but they are not readily articulated and mitigated by means of pluralist organization and bargaining.

Whether or not mass theorists are correct in this particular argument, the general principle is clear: "the differentiation . . . which disintegrates is very different from that which brings vital forces together" (Durkheim [1893] 1960, p. 353). The functional differentiation of structures may increase efficiency, but it simultaneously may disintegrate what was a viable social entity without creating the conditions for the formation of new social entities. A great deal depends upon whether a given social function can sustain a social identity or whether the function is so specialized or otherwise limited that it cannot provide sufficient meaning to summon commitment.

As organizations become very large, specialized, and removed from the network of social relations of their members, they lose their authoritative character. The modern trade union, for example, appears less capable of providing meaning and identity to its members than occupational associations of former times, so that its power may seem more arbitrary and less authoritative. When similar processes occur in the church, profession, corporation, and other secondary groups, the society begins to lose its pluralism and experiences a general dissolution of authority.

The decline of authoritative standards and leadership creates anxiety and insecurity; feelings of aimlessness and lack of social direction become widespread. Such a state of anomie generates the quest for new authority and heightens receptivity to pseudo-authority. As in the case of the search

for community, mass analysts try to identify the symptoms and consequences of inappropriate and inauthentic responses to genuine needs for authoritative standards and direction. The rise of charismatic leadership testifies to this need. But of greater significance is the quality of this leadership—whether it is the carrier of new values or merely the popularity of a demagogue or celebrity. Where mass media of communication and the techniques of manipulation and mobilization are highly developed, it hardly suffices to say that popular enthusiasm is sufficient to demonstrate a charismatic relationship. The conditions of mass society facilitate the fabrication of charisma in the absence of value commitment on the part of either leaders or masses.

More generally, whenever the claim to authority is based substantially on the manipulation of symbols rather than on the invoking of standards, one may speak of pseudo-authority. What concerns mass analysts are situations in which there is a marked discrepancy between the symbols and the substance of authority. The claim that public opinion is authoritative under conditions of modern mass democracy is a case in point. Where public opinion becomes a slogan for whatever is believed to be popular, rather than a process and product of public deliberation and discussion, it is a form of pseudo-democracy. This is a powerful tendency in mass society because of the difficulties of making and eliciting personal responses in mass arenas and bureaucratic institutions. The ease of mass manipulation and the difficulty of public deliberation favor the symbols of democracy without the substance, especially where the symbols are widely stereotyped in terms that do not invite close scrutiny or comparison with actual experience (Selznick 1952).

The most extreme manifestation of manipulated and mobilized opinion is found in totalitarian systems. The unanimous elections, the staged demonstrations, and the mass indoctrination programs reveal the possibilities of pseudo-democracy. Totalitarianism itself is greatly facilitated by the existence or creation of masses of people who are not attached to independent social groups. Indeed, the study of totalitarianism is instructive because it shows how the effort to mobilize a whole population actually *requires* the destruction of bonds of authority and community and their replacement by ideological organizations. However, the ultimate reliance of totalitarian regimes on the use of force testifies to the limits of this strategy of mobilization. Moreover, mass conditions do not by themselves produce totalitarianism. The existence of

modern technology plus the availability of large numbers of socially unintegrated people make totalitarianism possible, but a number of other conditions must be present to prepare the way for totalitarianism.

Theories of mass society are sometimes said to be prophecies of despair (Bell 1960; Shils 1962). But they need not be so construed. That the mass analyst tends to be a pathologist of contemporary society in no way denies the existence in that society of creative and value-sustaining social forces. Properly incorporated into social science, the concepts of mass society invite analysis of the conditions under which mass processes are strong or weak. Thus, mass analysis may take on new significance in alerting students of non-Western societies to certain pathologies of social development. Perhaps more important for social thought than any particular proposition of mass society is the concern this perspective represents for assessing the quality of culture and social institutions. If social science is to pursue this kind of inquiry, however, it will have to renew its communication with the humanities. For if the idea of mass society has greatly influenced social science, its formulation and development have been to a considerable extent the work of philosophy, history, and literature.

MATHEMATICAL STATISTICS

See STATISTICS.

MATHEMATICS

The history of mathematics, and to some extent its content, can be thought of as involving three major phases. Ancient mathematics, covering the period from the earliest written records through the first few centuries A.D., culminated in Euclidean geometry, the elementary theory of numbers, and ordinary algebra. Equally important, this phase saw the evolution and partial clarification of axiomatic systems and deductive proofs. The next major phase, classical mathematics, began more than 1,000 years later, with the Cartesian fusion of geometry and algebra and the use of limiting processes in the calculus. From these evolved, during the eighteenth and nineteenth centuries, the several aspects of classical analysis. Other contributions of this phase include non-Euclidean geometries, the beginnings of probability theory, vector spaces and matrix theory, and a deeper development of the theory of numbers. About a hundred years ago the third and most abstract and demanding phase, known as modern mathematics, began to evolve and become separate from the classical period. This phase has been concerned with the isolation of several recurrent structures of analysis worthy of independent study—these include abstract algebraic systems (for example, groups, rings, and fields), topological spaces, symbolic logic, and functional analysis (Hilbert and Banach spaces, for example)—and various fusions of these systems (for example, algebraic geometry and topological groups). The rate of growth of mathematics has been so great that today most mathematicians are familiar in detail with the major developments of only a few branches of the subject.

Our purpose is to give some hint of these topics. The reader interested in a somewhat more detailed treatment will find the best single source to be *Mathematics: Its Content, Methods, and Meaning*, the translation of a Russian work (Akademiia Nauk S.S.S.R. 1956). Other general works are Courant and Robbins (1941), Friedman (1966), and Newman (1956). More specific references are given where appropriate. We do not here discuss probability, mathematical statistics, or computation, even though they are especially important mathematical disciplines for the social sciences, because they are covered in separate articles in the encyclopedia.

Ancient mathematics

The history of ancient mathematics divides naturally into three periods. In the first period, the pre-Hellenic age, the beginnings of systematic mathematics took place in ancient Egypt and in Mesopotamia. Contrary to much popular opinion, the mathematical developments in Mesopotamia were deeper and more substantial than those in Egypt. The Babylonians developed elementary arithmetic and algebra, particularly the computational aspects of algebra, to a surprising degree. For example, they were able to solve the general quadratic equation, $ax^2 + bx + c = 0$. An authoritative and readable account of Babylonian mathematics as well as of Greek mathematics is presented by Neugebauer (1951).

The second period of ancient mathematics was the early Greek, or Hellenic, age. The fundamentally new step taken by the Greeks was to introduce the concept of a mathematical proof. These developments began around 600 B.C. with Thales, Pythagoras, and others, and reached their high points a little more than a century later in the work of Eudoxus, who is responsible for the theory of proportions, which in antiquity held the place now held by the modern theory of real numbers.

The third period is the Hellenistic age, which extended from the third century B.C. to the sixth century A.D. The early part of this period, sometimes called the golden age of ancient mathematics, encompassed Euclid's *Elements* (about 300 B.C.), which is the most important textbook ever written in mathematics, the work on conics by Apollonius (about 250 B.C.), and above all the extensive and profound work of Archimedes on metric geometry and mathematical physics (Archimedes died in 212 B.C.). The second most important systematic treatise of ancient mathematics, after Euclid's *Elements*, is Ptolemy's *Almagest* (about A.D. 150). Ptolemy systematized and extended Greek mathematical astronomy and its mathematical methods. The mathematical sophistication of Archimedes and the richness of applied mathematics evidenced by the *Almagest* were not equaled until the latter part of the seventeenth century.

Classical analysis

The intertwined and rapid growth of mathematics and physics during the seventeenth, eighteenth, and nineteenth centuries centered in a major way on what is now called classical analysis: the calculus of Newton and Leibniz, differential and integral equations and the special func-

tions that are their solutions, infinite series and products, functions of a complex variable, extremum problems, and the theory of transforms. At the basis of all this are two major ideas, *function* and *limit*. The first evolved slowly, beginning with the correspondence, established in the Cartesian fusion of the two best-developed areas of ancient mathematics, between algebraic expressions and simple geometric curves and surfaces, until we now have the present, very simple definition of the term "function." A set f of points in the plane (ordered pairs of numbers) of the form (x, y) is called a function if at most one y is associated with each x . If (x, y) is a member of f , it is customary to write $y = f(x)$; x is sometimes called the independent variable and y the dependent variable, but no causal meaning should be read into this terminology.

The notion and notation may be generalized to more than one independent variable; if g is a set of ordered triples (x, y, z) with at most one z associated with each pair (x, y) , then $z = g(x, y)$ is called a function of two arguments. Since the most general notion of function can relate any two sets of objects, not just sets of numbers, it is sometimes desirable to emphasize the numerical character of the function. Then f is said to be a real-valued function of a real variable; here the term "real" refers to real numbers (in contrast to complex numbers, which will be discussed later).

Although a real-valued function has been defined as a set of ordered pairs of numbers, (x, y) , where the domain of x is an unspecified set of numbers, the subsequent discussion of functions is mostly confined to the familiar case in which the domain of x is an interval of numbers. Even when the discussion applies more generally, it is helpful to keep the interval case in mind.

A desire to understand limits was apparent in Greek mathematics, but a correct definition of the concept eluded the Greeks. A fully satisfactory definition, which was not evolved until the nineteenth century (by Augustin Louis Cauchy), is the following: b is the limit of f at a if and only if for every positive number ϵ there is a positive number δ such that, when the absolute value of $x - a$ is less than δ and greater than 0 (that is, $0 < |x - a| < \delta$), the absolute value of $f(x) - b$ is less than ϵ (that is, $|f(x) - b| < \epsilon$). In other words, b is the limit of f at a if x can be chosen sufficiently close to a (but not equal to a) to force $f(x)$ to be as close to b as desired. Symbolically, this is written $\lim_{x \rightarrow a} f(x) = b$. The limit of f at a may exist even though $f(a)$ is not defined; moreover, when $f(a)$ is defined, b may or may not equal $f(a)$. If it does—that is, if $f(x)$ is "near" $f(a)$ whenever x is "near" a —then f is

Figure 1 — Approximation of the derivative of $f(x)$

said to be continuous at a . If f is continuous at each a in an interval, f is said to be continuous over that interval.

The calculus. The calculus defines two new concepts, the derivative and the integral, in terms of function and limit. They and their surprising relationship serve as the basis of the rest of mathematical analysis.

The derivative. The first definition arises as the answer to the question "Given a function f , what is its slope (or, equivalently, its direction or rate of change) at any point x ?" For example, suppose that $y = f(x)$ represents the distance, y , that a particle has moved in x units of time; then what is the rate of change of distance—the instantaneous velocity—at time x ? If h is a short period of time, then an approximate answer is the distance traversed between x and $x + h$, that is, $f(x + h) - f(x)$, divided by the time, h , taken to travel that distance (see Figure 1). The approximation is better the smaller the value of h , which suggests the definition of the rate of change of f at x as the limit of this ratio as h approaches 0, that is,

$$\lim_{h \rightarrow 0} \frac{f(x + h) - f(x)}{h}.$$

This limit, if it exists, is denoted by $f'(x)$ (or by $df(x)/dx$ or by dy/dx) and is called the *derivative* of f at x . If $f'(x)$ exists, then f can be shown to be continuous at x , but the converse is not true in general.

One of the earliest and most important applications in the social sciences of the concept of a derivative has been to the mathematics of marginal concepts in economics. For example, let x represent output, $C(x)$ the cost of output x , and $R(x)$ the revenue derived from output x ; then $C'(x)$ and

$R'(x)$ (or $dC(x)/dx$ and $dR(x)/dx$) are the marginal cost and marginal revenue, respectively. Marginal utility, marginal rate of substitution, and other marginal concepts are defined in a similar fashion. Many of the fundamental assumptions of economic theory receive precise formulation in terms of these marginal concepts.

The integral. The second concept in the calculus arises as the answer to the question "What is the area between the graph of a function f and the line $y = 0$ (the horizontal axis, or abscissa, of the coordinate system) over the interval from a to b ?" (Regions below the abscissa are treated as negative areas to be subtracted from the positive ones above the abscissa; see Figure 2.) The solution, which will not be stated precisely, involves the following steps: the abscissa is partitioned into a finite number of intervals; using the height of the function at some value within each interval, the function is approximated by the resulting step function; the area under the step function is calculated as the sum of the areas of the rectangles of which it is composed; and, finally, the limit of this sum is calculated as the widths of the intervals approach zero (and, therefore, as their number approaches infinity). When this limit exists, it is called the *Riemann integral* of f from a to b and is symbolized as $\int_a^b f(x) dx$. It can be shown that the Riemann integral exists if f is continuous over the interval; it also exists for some discontinuous functions. For more advanced work, the concept of the length of an interval is generalized to the concept of the *Lebesgue measure* of a set, and the Riemann integral is generalized to the *Lebesgue integral*. Roughly, the vertical columns used to approximate the area in the Riemann integral are replaced in the Lebesgue integral by horizontal slabs.

Although the interpretation of the integral as an extension of the elementary concept of area is

Figure 2 — Approximation of the integral of $f(x)$

important, even more important is its relation (called the fundamental theorem of the calculus) to the derivative: Consider $F(x) = \int_a^x f(u) du$ as a function of the upper limit, x , of the interval over which the integral is computed; it can then be proved that the derivative of this function, $F'(x)$, exists and is equal to $f(x)$. Put another way, the rate of change at x of the area generated by f is equal to the value of f at x ; or put still another way, the operation of taking the derivative undoes the operation of integration. This fact plays a crucial role in the solution of many problems of classical applied mathematics that are formulated in terms of derivatives of functions.

Introductions to the calculus and elementary parts of analysis are Apostol (1961-1962) and Bartle (1964).

Implicit definitions of functions. An algebraic equation such as $2x^2 - 5x - 3 = 0$ implicitly defines two numbers (namely, the two values of x , 3 and $-\frac{1}{2}$) for which the equality holds. Other algebraic equations implicitly define sets of numbers for which they hold.

A functional equation is an equality stated in terms of an unknown function; it implicitly defines those functions (as in the algebraic case, there may be more than one) that render the equality true.

Ordinary differential equations. Suppose it is postulated that the amount of interest (that is, the rate of change of money at time t) is proportional to (that is, is a constant fraction, k , of) the amount, $f(t)$, of money that has been saved. (This is the case of continuous compound interest.) Then f satisfies the equation $f'(t) = kf(t)$. This is a simple example of an *ordinary differential equation*, the solution of which is any function having the property that its derivative is k times the function. The solutions are $f(t) = f(0) \exp(kt)$, where $f(0)$ denotes the initial amount of money at time $t = 0$. Another simple economic example is the differential equation that arises from the assumption that marginal cost always equals average cost (that is, $dC(x)/dx = C(x)/x$) which has the solution that average cost is constant, that is, that $C(x) = kx$ for some constant, k .

Some laws of classical physics are formulated as second-order, linear, ordinary differential equations of the form

$$f''(t) + P(t)f'(t) + Q(t)f(t) = R(t),$$

where f'' is the derivative of f' (f'' is called the second derivative of f) and P , Q , and R are given functions. If, for example, f denotes distance, then this differential equation asserts that at each time t , a linear relation holds among distance, velocity,

and acceleration. A vast literature is concerned with the solutions to this class of equations for different restrictions on P , Q , and R ; most of the famous special functions used in physics—Bessel, hypergeometric, Hankel, gamma, and so on—are solutions to such differential equations (see Codrington 1961).

Partial differential equations. Many physical problems require differential equations a good deal more complicated than those just mentioned. For example, suppose that there is a flow of heat along one dimension, x . Let $f(x, t)$ denote the temperature at position x at time t . With t fixed, one can find the rate of change (the derivative) of temperature with changes in x ; denote this by $\partial f(x, t)/\partial x$ and its second derivative with respect to x by $\partial^2 f(x, t)/\partial x^2$. These are called partial derivatives. Similarly, holding x fixed, the derivative with respect to t is denoted by $\partial f(x, t)/\partial t$. According to classical physics, temperature changes due to conduction in a homogeneous one-dimensional medium satisfy the following *partial differential equation*:

$$\frac{\partial f(x, t)}{\partial t} = \frac{k}{\rho\sigma} \frac{\partial^2 f(x, t)}{\partial x^2},$$

where k is the thermal conductivity, ρ the density, and σ the specific heat of the medium. Problems involving two or more independent variables (usually, time and some or all of the three space coordinates)—fluid flow, heat dissipation, elasticity, electromagnetism, and so on—lead to partial differential equations. Their solution is often very complex and requires the specification of the unknown function along a boundary of the space. This requirement is called a *boundary condition*. (See Akademiia Nauk S.S.S.R. [1956] 1964, chapter 6.)

Integral equations. Some physical problems lead to *integral equations*. In one type, functions g and K of one and two variables, respectively, and a constant, λ , are given, and the problem is to find those functions, f , for which

$$f(x) = g(x) + \lambda \int_a^b K(x, y) f(y) dy.$$

This equation is called Fredholm's linear integral equation or the inhomogeneous linear integral equation. Basically, it asserts that the value of some quantity f at a point x is equal to an impressed value, $g(x)$, plus a weighted average of its value at all other points. Integral equations arise in empirical contexts for which it is postulated that the value of a function at a point depends on the behavior of the function over a large region of its domain. Thus, in the example just considered the value of f at x depends on the in-

tegrand $K(x, y)f(y)$ integrated over the interval (a, b) . There is a large body of literature dealing with the solution of various types of integral equations, especially those of interest in physics and probability theory.

Functional equations. Although both differential and integral equations (and mixtures of the two, called integrodifferential equations) are examples of functional equations, that term is often restricted to equations that involve only the unknown function, not its derivatives or integrals. A simple, well-known example is $f(xy) = f(x) + f(y)$, which implicitly defines those functions that transform multiplication into addition. If f is required to be continuous, then the solutions are $K \int_1^x dz/z$, where K is a positive constant; this integral is called the natural logarithm. The choice of K is usually referred to as the selection of the base of the logarithm.

Difference equations are functional equations of special importance in the social sciences. They arise both in the study of discrete stochastic processes (in learning theory, for example) and as discrete analogues of differential equations. Here the unknown function is defined only on the integers (or, equivalently, on any equidistant set of points), not on all of the real numbers, and so the function is written $f_n = f(n)$, where n is an integer. The equation states a relation among values of the unknown function for several successive integers. For example, the second-order, linear difference equation—the analogue of the second-order, linear, ordinary differential equation, described above—is of the form

$$f_{n+2} + P_n f_{n+1} + Q_n f_n = R_n.$$

In some probabilistic models of the learning process it is postulated (or derived from more primitive assumptions) that the probability of a particular response on trial $n + 1$, denoted by p_{n+1} , is some function of p_n and of the actual events that occurred on trial n . The simplest such assumption is the linear one, that is, $p_{n+1} = \alpha p_n + \beta$, where α and β are parameters that depend upon the events that actually occur. If there is a run of trials during which the same events occur, so that α and β are constant, then the solution to the above first-order, linear difference equation is

$$p_k = \alpha^k p_0 + \frac{(1 - \alpha^k)}{1 - \alpha} \beta.$$

When different events occur on different trials, the equation to be solved becomes considerably more complex. An introduction to difference equations is Goldberg (1958).

Given a functional equation—in the most gen-

eral sense—the answer to the question of whether a solution exists is not usually obvious. Exhibiting a solution, of course, answers the question affirmatively, but often the existence of a solution can be proved before one is found. Such a result is known as an *existence theorem*. If a solution exists, it is also not usually obvious whether it is unique and, if it is not unique, how two different solutions relate to one another. A statement of the nature of the nonuniqueness of the solutions is known, somewhat inappropriately, as a *uniqueness theorem*. Some rather general existence and uniqueness theorems are available for differential and integral equations, but in less well understood cases considerable care is needed to discover just how restrictive the equation is.

A general work on functional equations is Aczél (1966).

Three other areas of classical analysis. Three other branches of classical analysis will be briefly discussed.

Extremum problems. For what values of its argument does a function assume its maximum or its minimum value? This type of problem arises in theoretical and applied physics and in the social sciences. In its simplest form, a real-valued function f is defined over some interval of the real numbers, and the problem is to find those x_0 for which $f(x_0)$ is a maximum or a minimum. If f is differentiable and if x_0 is not one of the end points of the interval, a necessary condition is that $f'(x_0) = 0$; moreover, x_0 is a local maximum if $f''(x_0) < 0$ and a local minimum if $f''(x_0) > 0$. (These statements should be intuitively clear for graphs of simple functions.) From these results it is easy to find, for example, which rectangle has the maximum area when the perimeter is held constant: it is the square whose sides are each equal to a quarter of the perimeter.

A much more difficult and interesting problem—the subject of the *calculus of variations*—is to find which function (or functions) f of a given family of functions causes a given function F of f (known as a functional) to assume its maximum or minimum value. For example, let f be a continuous function that passes through two fixed points in the plane, and let $F(f)$ be the surface area of the body that is generated by rotating f about the abscissa. A question that may be asked is “For which f (or f ’s) is $F(f)$ a minimum?” A major tool in the solution of this problem is a second-order, ordinary differential equation, known as Euler’s equation, that f must necessarily satisfy (just as the solution x_0 to the simpler problem necessarily satisfies $f'(x_0) = 0$). (See Akademiia Nauk S.S.S.R. [1956] 1964, chapter 8.)

Within the past twenty years new classes of extremum problems have been posed and partially solved; they are mainly of concern in the social sciences, and they go under the names of linear, nonlinear, and dynamic programming. An example of a linear programming problem is the following diet problem. Each of several foodstuffs, f_1, f_2, \dots, f_k , contains known amounts of various nutritional components, such as vitamins and proteins. Let f_{ij} be the amount of component j in food f_i , $j = 1, 2, \dots, n$, and let a_j be the minimum amount of component j acceptable in the diet. If x_i is the amount of food f_i in the diet, the diet will be acceptable only if the following n inequalities are fulfilled:

$$x_1 f_{1j} + x_2 f_{2j} + \dots + x_k f_{kj} \geq a_j, \quad j = 1, 2, \dots, n.$$

If p_i denotes the price of food f_i , the problem is to choose the x_i so as to minimize the cost,

$$x_1 p_1 + x_2 p_2 + \dots + x_k p_k,$$

while fulfilling the above linear inequalities. [See PROGRAMMING.]

Functions of a complex variable. One of the most beautiful subfields of analysis is the theory of functions of a complex variable, which was developed in the nineteenth century, starting with the work of Cauchy. It has been significant in the growth of several two-dimensional, continuous physical theories, including parts of electromagnetism, hydrodynamics, and acoustics, but so far its applications in the social sciences have been mainly restricted to mathematical statistics, as in the concept of the characteristic function of a probability distribution. A complex number, z , is of the form $z = x + iy$, where x and y are real numbers and $i = \sqrt{-1}$. Sums and products are defined in such a way that the resulting arithmetic reduces to that of the ordinary numbers when $y = 0$. Because a point (x, y) in the plane can be (usefully) identified with the complex number $x + iy$, functions from the plane into the plane can be interpreted as complex-valued functions of a complex variable. If the derivative of such a function exists at all points of a region, derivatives of all orders exist and the function can be expressed as a convergent *power series* of the form $a_0 + a_1 z + a_2 z^2 + \dots$ for some circle of z ’s within that region. It is clear from this result that the mere supposition that the derivative exists is a much stronger condition for complex-valued functions than for ordinary numerical functions. Such functions, which are called *analytic*, are very strongly constrained—among other things, specifying an analytic function over a small region determines it completely—and this fact has been

effectively exploited to solve many two-dimensional problems of theoretical and practical interest. Interestingly, the theory cannot be neatly generalized beyond two dimensions. An introductory work on functions of a complex variable is Cartan (1961).

Integral transforms. Suppose that f is any continuous, real-valued function defined over an interval from a to b and that K is a fixed, continuous, real-valued function of two variables, the first of which is also on the interval from a to b ; then $I(f, y) = \int_a^b K(x, y)f(x)dx$ is called an *integral transform* of f . If K satisfies certain restrictions, knowing I is equivalent to knowing f . Nevertheless, if K is carefully chosen, I may have convenient properties not possessed by f . For example, if $a = 0$, $b = \infty$, and $K(x, y) = e^{-xy}$, then I , which is then known as the *Laplace transform* and which is closely related to the moment-generating function of statistics, has the property that it converts certain integrals (convolutions) of two functions into multiplications of their transforms. In statistics such a convolution represents the distribution of the sum of two independent random variables. Another well-known and important example is the *Fourier transform*, which is used widely in statistics, and to a lesser extent in probabilistic models of behavior, to obtain a probability distribution from its characteristic function.

Theory of numbers

Despite several intellectual crises that led mathematicians to introduce new types of numbers into mathematics, it was not until about a hundred years ago that numbers were treated as being something other than intuitively understood. The natural numbers, 1, 2, 3, ..., and their ratios, the positive rationals, are ancient concepts. The Greeks first noted their incompleteness when they showed that they are inadequate to represent $\sqrt{2}$, the length of the diagonal of a square whose side is of length 1. Certain irrational numbers had to be added, and later 0, negative numbers, and complex numbers were added so that certain classes of equations would all have solutions. To clarify this patchwork and to understand the uniqueness of the additions, nineteenth-century mathematicians undertook the axiomatization of various aspects of the number system. Perhaps the most subtle step was the definition of irrational numbers in terms of sets of rational numbers (roughly, the set of all rationals less than the irrational to be defined).

The axiomatization of numbers is not really the mainstream of the "theory of numbers." When one sees a book or course with that title, it usually refers to the study of properties of the natural numbers, mainly the prime numbers. Recall that

an integer is prime if it is divisible only by 1 and itself; the first few primes are 3, 5, 7, 11, and 13. In addition to the many results that can be proved directly (some of which were known to the ancients), such as that every integer can be represented uniquely as the product of powers of primes and that there are infinitely many primes, other results have depended upon the application of deep results from analysis. For example, parts of the theory of functions of a complex variable were used to show that the number of primes not larger than n divided by the number $n/\ln n$, where $\ln n$ is the natural logarithm of n , that is, $\int_1^n dx/x$, is a ratio that approaches 1 as n becomes large. Not only has this work greatly increased the depth of understanding of integers, but it has fed back into analysis and was one of the factors leading to the development of parts of contemporary abstract algebra.

Many applications of mathematics (for example, in statistics) involve counting the number of distinct events or objects that satisfy certain conditions; often these counting problems are quite difficult. Theorems providing explicit formulas or recursion schemes are called combinatorial theorems. One of the earliest important examples was the binomial theorem for the expansion of $(a + b)^n$, which is now part of every elementary algebra course. [See PROBABILITY, article on FORMAL PROBABILITY.]

A general introduction to the theory of numbers is Ore (1948).

Algebra

Classically, algebra was the theory of solving equations expressed in terms of the four arithmetical operations—addition, subtraction, multiplication, and division. The linear and quadratic equations of elementary algebra are familiar examples. Historically, the expression of mathematical problems in the form of equations, using letters to stand for the unknown numbers, was a major step in clarifying and simplifying the mathematical nature of many kinds of problems. Perhaps the most important consequence of the introduction of letters and the use of equations was the extension of routine methods of calculation to quite complicated settings. The introduction of algebraic equations probably ranks in importance in the history of ideas with the earlier invention, probably first by the Babylonians, of the place-value system of notation for numbers. Such a system was needed to develop simple algorithms for performing arithmetical computations.

The general theory of algebraic equations, the elementary parts of which are studied in high

school, has a long and distinguished history in mathematics. The proof by Niels Henrik Abel in 1824 that solutions of an algebraic equation of degree five or greater, where the degree is the highest exponent of any term in the equation, cannot be expressed in terms of radicals (that is, expressions definable in terms of square roots) was one of the most important mathematical results of the first half of the nineteenth century. Another result of basic importance is the fundamental theorem of algebra, which was first proved in the eighteenth century but which was proved rigorously only in the last half of the nineteenth century. This theorem asserts that every algebraic equation always has at least one root that is a real or a complex number. Also of great significance were the proofs that not all numbers are roots of algebraic equations; numbers that are not such roots are called transcendental numbers. The most famous proofs of this sort are Charles Hermite's (in 1873) that e is transcendental and F. Lindemann's (in 1882) that π is transcendental.

Orderings. Much of the work in algebra during the present century has been devoted to generalized mathematical systems that are characterized not in terms of the four fundamental arithmetical operations but in terms of generalizations of these operations and of the familiar ordering relations of "less than" and "greater than."

In a number of the social sciences the theory of binary relations has received extensive application. From an algebraic standpoint a *binary relation structure* may be characterized as consisting of a set A and a set R of ordered pairs (x, y) , where x and y are both elements of A . Such an R is called a binary relation on A . A relation R is said to be a *partial ordering* of A when it is reflexive, antisymmetric, and transitive—that is, when it satisfies the following three properties: *reflexive*: for every x in A , xRx ; *antisymmetric*: for every x and y in A , if xRy and yRx , then $x = y$; *transitive*: for every x , y , and z in A , if xRy and yRz , then xRz . If R is also connected in A (that is, if for any two elements x and y in A with $x \neq y$, either xRy or yRx) then R is said to be a *complete* or *simple ordering* or, sometimes, a *linear ordering* of A . The concept of a complete ordering is a direct abstraction of the order properties of " \leq " with respect to the real numbers. A familiar use of the concept of an ordering relation is in utility theory, particularly in the classical theory of demand in economics, in which it is assumed that each individual has an ordering relation over the set of commodity bundles or, more generally, over the set of alternatives with which he is presented. The general concept of ordering relations also has far-ranging applications

in the theory of measurement within psychology and sociology, and more general binary relations have been extensively applied in anthropology in the study of kinship systems.

Partial orderings can be extended in another direction by imposing additional conditions to obtain *lattices*, which have also been used in the social sciences. In a different direction, but still within the framework of binary relations, is the *theory of graphs*, in which no restrictions are placed on the binary relation, R . Applications of graph theory have been made to social-psychological and sociological problems, especially to provide a mathematical method for representing various kinds of relationships between persons.

Groups, rings, and fields. Another direction of generalization of classical algebra has been to what are called groups, rings, and fields. A *group* is a set A together with a binary operation, \circ , satisfying the following axioms. First, the operation \circ is associative, that is, for x , y , and z in A , $x \circ (y \circ z) = (x \circ y) \circ z$. Second, there is an element e , called the identity, of the set A such that for every x in A , $x \circ e = e \circ x = x$. And, finally, for each element x of A there is an inverse element x^{-1} such that $x \circ x^{-1} = e$. It is obvious that if A is taken as the set of integers, \circ as the operation of addition, e as the number 0, and the inverse of x as the negative of x , then the set of integers is a group under the binary operation of addition. The theory of groups has had profound ramifications in other parts of mathematics and in the sciences, ranging from the theory of algebraic equations to geometry and physics. The reason for the fundamental importance of group theory is perhaps best summarized by stating that a group is the appropriate way to formulate the very important concept of symmetry. In the range of applications of group theory just mentioned, the underlying thread is the concept of symmetry, whether it is in the symmetry of the roots of an equation or the symmetry properties of the fundamental particles of physics. As a simple example, consider the finite group of rotations 90° , 180° , 270° , and 360° . A square does not change its apparent orientation under such a rotation about its center, but an equilateral triangle does. This group of rotations is the symmetry group of rotations for a square but not, of course, for an equilateral triangle. Although the methods and results of group theory have not yet had special applications of depth in the social sciences, they are important to many of the general mathematical results that have been applied.

The theories of rings and fields represent rather direct generalization of arithmetical properties of the number system. The theory of groups is fun-

damentally a generalization of the concept of a single binary operation, such as addition or multiplication, whereas rings and fields are algebraic systems that have two fundamental operations. The most familiar example of a field or of a ring is the set of rational numbers or of real numbers with respect to the operations of addition and multiplication.

Boolean algebras. Algebraic aspects of the theory of sets have been studied under the heading of Boolean algebras. The concept of an algebra of sets, that is, a collection of sets closed under union and complementation, is fundamental in the modern theory of probability, where events are interpreted as sets of possible outcomes and numerical probabilities are assigned to events. [See PROBABILITY, *article on FORMAL PROBABILITY.*]

Isomorphism and homomorphism. It should be mentioned that certain very general mathematical concepts find their most natural definition and application in modern algebra. One of the most important concepts is that of the isomorphism of two mathematical systems. An *isomorphism* is a one-to-one mapping of a system A onto a system B in which the operations and relations of A are preserved under the mapping and have the same structure as the operations and relations of system B . If the mapping is not one-to-one but the operations and relations are preserved, then it is called a *homomorphism*. A well-known application of the concept of isomorphism in the social sciences is in theories of fundamental measurement in which one shows that an appropriate algebra of empirical operations is isomorphic to some numerical algebra. It is this isomorphism that permits the direct application of computational methods to the results of measurement.

Introductory works on algebra, both for this and for the next section, are Birkhoff and MacLane (1941) and Mostow, Sampson, and Meyer (1963).

Vector spaces and matrix algebra

Linear algebra is one of the most important generalizations of classical elementary algebra. The objects to which the operations of addition and multiplication are applied are now matrices, vectors of an n -dimensional space, and linear transformations (an $n \times n$ matrix is a particular representation of a linear transformation in n -dimensional space). More particularly, linear algebra arises as a generalization of the linear equations so familiar in elementary algebra, and historically one of the most important tasks of linear algebra has been to find solutions of systems of linear equations. As many research workers in the social sciences know,

the numerical solution of linear equations can be an extremely laborious and difficult affair when the number of equations is large. The set of coefficients of a system of linear equations gives rise to the concept of a rectangular array of numbers, which is precisely what a matrix is. An algebra of matrices in terms of addition and multiplication may be constructed; the distinguishing feature of this algebra, as compared with the algebra of the real numbers, is that multiplication is not commutative—that is, \mathbf{AB} is not usually equal to \mathbf{BA} , and the product of two nonzero matrices can be zero.

The intuitive geometric concept of a vector may be represented by a column or row of n numbers, and an algebra of vectors, which bears a close resemblance to the algebra of numbers, may be constructed. Simple (linear) transformations of vectors, such as rotations and stretches of the coordinate system in space, can be interpreted as multiplication by matrices. The interaction between the geometrical intuitions about n -dimensional space and the algebraic techniques of calculation provided by linear algebra and the theory of matrices have made them powerful tools in the application of mathematics to many parts of science. These applications have been particularly prominent in statistics (for example, in factor analysis), as well as in economics, where it is often useful to treat n -dimensional bundles of commodities as vectors.

Topology and abstract spaces

Intuitively, a topological transformation of a geometrical figure or object is a deformation that introduces neither breaks nor fusions in the object. Put more exactly, a topological transformation is one that is one-to-one, is continuous, and has a continuous inverse. If one starts with a circle—perhaps the best example of a simple closed curve—one can deform it topologically into an ellipse or into the shape of a crescent, but one cannot deform it topologically into a figure eight, for example, because then two distinct points of the circle are fused as the intersection point of the eight. Also, one cannot deform it into a straight line segment, because to do so would introduce a break in the circle. Many familiar qualitative geometrical properties are topological invariants in the sense that they are not altered (are invariant) under topological transformations. Examples are the property of being inside or outside a closed figure in the plane; the property of a surface being closed, such as the surface of a sphere or an ellipsoid; or the property of the dimension of an object. For example, the surface of a sphere cannot be

topologically transformed into a one-dimensional curve or a three-dimensional sphere. We shall not attempt here to give an exact definition of continuity as it is used in topology; we simply remark that it is a reasonable generalization of the concept of continuity used in analysis.

Topological methods and results have far-reaching applications in many branches of mathematics, but as yet the methods themselves have not been directly applied in those parts of the social sciences concerned extensively with empirical data. The most direct applications have been in economics, where topological fixed-point theorems have been of great importance in investigating the conditions guaranteeing the existence of a stable equilibrium in a competitive economy. The classical example of a fixed-point theorem—first proved by L. E. J. Brouwer, at the beginning of this century—states that for every topological mapping of an n -dimensional sphere into itself there is always at least one point that maps into itself, that is, remains fixed. Familiar examples of such mappings are rotations in two or three dimensions for which the center of the rotation is the fixed point of the transformation.

Topological space. As a typical example of abstraction in modern mathematics, the initial concept of a topological transformation of familiar geometrical figures has led to the general abstract notion of a topological space. Roughly speaking, a *topological space* consists of a set, X , and a family, \mathcal{G} , of subsets of X , called *open sets*, for which the following four conditions are satisfied: the empty set is in \mathcal{G} ; X is in \mathcal{G} ; the union of arbitrarily many sets each of which is in \mathcal{G} is also in \mathcal{G} ; and the intersection of any finite number of sets from \mathcal{G} is also in \mathcal{G} . The concept of an open set is a generalization of the notion of an open interval of real numbers (an interval that does not include its end points). For example, the natural topology of the real line is the family of open intervals together with the sets that are formed from arbitrary unions and finite intersections of open intervals. Generally speaking, the notion of open set is used to express the idea of continuity. The important thing about a continuous function is that it does not jumble neighboring points too much, and this requirement may be expressed by requiring of a topological transformation that open sets be mapped into open sets and that the inverse of an open set be an open set.

Metric space. Other kinds of abstract spaces have come into prominence in the development of topology. Perhaps the most important is the concept of a metric space. A set, X , together with a

distance function, d , that maps pairs of points into real numbers is called a *metric space* if d satisfies the following conditions: $d(x, y) = 0$ if and only if $x = y$, that is, the distance between x and y is 0 if and only if x and y are the same point; $d(x, y) \geq 0$, which asserts that distance is a non-negative real number; $d(x, y) = d(y, x)$, that is, distance is symmetric; and, finally, $d(x, y) + d(y, z) \geq d(x, z)$, which is known as the triangle inequality. The concept of a metric space has had important applications in many parts of mathematics and is a fundamental concept in modern mathematics. It has been applied in recent work in scaling theory in psychology and sociology, particularly to the problems of multidimensional scaling, and also in certain areas of mathematical economics [see SCALING]. It is clear that the notion of a metric space generalizes, in a very natural way, the concept of distance in Euclidean space.

A typical metric problem raised in the social sciences is this: Given data in the form of "distances" among a finite set of points, what is the smallest dimensional Euclidean space within which the points can be embedded so that these distances equal the Euclidean or some other preassigned metric of that space? Recently this problem has been effectively generalized by permitting certain transformations of the "distances" that preserve their metric property. Little has yet been done about embeddings in non-Euclidean spaces.

An introductory work on topology is Hocking and Young (1961).

Foundations

As was remarked above, the concept of a rigorous mathematical proof originated in ancient Greek mathematics. The modern formal axiomatic method, characteristic of twentieth-century mathematical research and one of the most important topics to be clarified in modern research on foundations of mathematics, is conceptually very close to the approach followed in Euclid's *Elements*. The main difference is that the primitive concepts of the theory are now treated as undefined or meaningless. All that is assumed about them must be formally expressed in the axioms. In contrast, in the *Elements* primitive concepts such as those of point and line are given an interpretation or meaning from the very beginning. This modern conception originated with David Hilbert, who provided the first complete, modern axiomatization of geometry in 1889. It is customary to say that the concepts of the theory are implicitly defined by the axioms. What is not recognized often enough is that the collection of axioms together *explicitly* de-

finer the theory embodied in the concepts. Thus, in slightly more exact phrasing, the axioms of Euclidean geometry define the theory of Euclidean geometry by defining the phrase "is a model of Euclidean geometry." In the same fashion, the axioms of group theory define the theory of groups by specifying what kinds of objects are called groups or, in other words, what kinds of objects are models of the theory of groups (here we are using the term "model" in the logical or mathematical sense).

A more particular aim of foundational research has been to provide a set of axioms that would serve as a basis for the main body of mathematics. At least three major positions on the foundations of mathematics have been enunciated in the twentieth century; they differ in their conception of the nature of mathematical objects.

Intuitionism. Intuitionism holds that in the most fundamental sense mathematical objects are themselves thoughts or ideas. The intuitionist holds that one can never be certain that he has correctly expressed the mathematics when it is formalized as a mathematical theory. As part of this thesis, the classical logic of Aristotle, in particular the law of excluded middle, has been challenged by Brouwer and other intuitionists because it permits the derivation of purely existential, nonconstructive statements about mathematical objects. In particular the validity of classical *reductio ad absurdum* proofs depends upon this logical law. Although intuitionists express themselves in a way which suggests a psychological analysis of mathematics, it should be emphasized that their conception of mathematical objects as thoughts has not been seriously explored by any intuitionists from the standpoint of scientific psychology.

Platonism. A second view of mathematics, the Platonistic one, is that mathematical objects are abstract objects that exist independently of human thought or activity. Those who hold that set theory or logic itself provides an appropriate foundation for mathematics (adherents of logicism) usually adopt some form of Platonism in their basic attitude. From the standpoint of working mathematics, set theory—and thus Platonism—has been the most influential conception of mathematics in this century. Set theory itself originated in the late nineteenth century with the revolutionary work of Georg Cantor. Its foundations were called into question by Bertrand Russell's discovery of a simple paradox which arises in considering the set of all objects that are not members of themselves. If it is supposed that to every property there corre-

sponds the set of objects having this property, then a contradiction within classical logic may easily be derived by considering the set whose members are those and only those sets that are not members of themselves. An apparently satisfactory foundation for set theory, which avoids this and related paradoxes, was formulated in 1908 by Ernst Zermelo, and with suitable technical extensions it provides a satisfactory basis for most of the mathematics published in this century.

Formalism. The third influential position on the foundation of mathematics, called formalism, was developed by Hilbert and others. This view is that the primary mathematical objects are the symbols in which mathematics is written. This carries to the extreme the development of the axiomatic method begun by the Greeks. Under the formalist account the interpretation and use of mathematics must then be given from outside pure mathematics. From a psychological or behavioral standpoint, there is much that is appealing about formalism, but again little effort has yet been made to relate the detailed results and methods of formalism to theoretical or experimental work in scientific psychology.

Relevance of research on foundations. In view of the high degree of agreement about the validity of most published pieces of mathematics, the skeptical social scientist may question the real relevance of these varying views about the foundations of mathematics to working mathematics itself. There is a highly invariant content of mathematics recognized by almost all mathematicians, including those concerned with the foundations of mathematics, and this invariant content is essentially untouched by radically different philosophical views about the nature of mathematical objects. A reasonable conjecture is that future research in the foundations of mathematics will attempt to capture this invariant content by concentrating on the character of mathematical thinking rather than on the nature of mathematical objects.

One other important aspect of foundational research in the twentieth century is the fundamental work on mathematical logic, in particular the attempt by Gottlob Frege, A. N. Whitehead, Bertrand Russell, and others to reduce all of mathematics to purely logical assumptions. These efforts have led to great clarification of the nature of mathematics itself and to vastly increased standards of precision in talking about mathematical proofs and the structure of mathematical systems. Of major importance were the deep results of Kurt Gödel (1931) on the logical limitations of any formal system rich

enough to express elementary number theory. His results show that any such formal system must be essentially incomplete in the sense that not all true sentences of the theory can be proved as theorems.

An introductory work on foundations is Kneebone (1963).

Mathematics applied to social sciences

Applications of mathematics to specific social science problems are described, and detailed references are given, elsewhere in this encyclopedia. That material is not repeated here; several reasonably general references are Allen (1938), Coleman (1964), Kemeny and Snell (1962), Luce (1964), Luce, Bush, and Galanter (1963-1965), Samuelson (1947). Suffice it to say that these applications involve only fragments of the whole of mathematics, and they have not been as successful as those in the physical sciences. The reasons are many, among them these: the effort so far expended is much less; the basic empirical concepts and variables have not been isolated and purified to the same degree; mathematics grew up with and was to some extent molded by the needs of physics, and so it may very well be less suited to social science problems if these problems are of a basically different character from those of physics; a typical social science problem appears to involve more variables than one is accustomed to handling in physics; and, finally, social scientists are generally not extensively trained in mathematics.

A social scientist who attempts to formulate and solve a scientific problem in mathematical terms is often disappointed with the mathematics he can find. This may happen simply because a mathematical system appropriate to his problem does not seem to have been invented, or, as is more common, the definite and often quite complex mathematical system that he happens to want to understand in depth has not been investigated in any detail. In this century especially, mathematicians have tended to focus on very general classes of systems, and the theorems concern properties that are true of all or of large subclasses of them; however, these results do not usually provide much detailed information about any particular member of the class.

As an example, the axioms of group theory are not categorical—that is, two groups need not be isomorphic. Therefore, theorems about groups in general tell one little about the specific properties of a particular group. But this is what is of interest when a particular group is used to represent an empirical structure, as in modern particle physics.

When this happens, it is necessary for the applied mathematician to carry out considerable mathematical analysis to achieve the understanding he needs to answer scientifically interesting questions.

We have already discussed two parts of mathematics in which highly specific systems have been explored in depth: classical analysis and matrix algebra. A primary motivation for this detailed work was the needs of physical science. In fortunate instances, a problem may be formulated in terms of one of these systems, in which case specific results can sometimes be extracted from the existing literature. Examples where this has been done are in the application of matrix algebra to factor analysis and of Markov chains (a part of probability theory) to several areas, including learning, social interaction, and social structure [see FACTOR ANALYSIS; MARKOV CHAINS].

Theory as detailed as this, however, is not typical of contemporary mathematics. We have in mind such active areas as associative and non-associative algebras, homological algebra, group theory, topological groups, algebraic topology, rings, manifolds, and functional analysis.

The generality of contemporary mathematics can be seductive in that it invites sophisticated treatments of scientific problems. It is often not difficult to find some general branch of mathematics within which to cast a specific social or behavioral problem without, however, actually capturing in detail the various constraints of the problem. Without these constraints few explicit results and predictions can be proved. Nevertheless, the real emptiness of such endeavors can be shrouded for the unwary in the impressive symbolism and ringing terms of whatever mathematics it is that is not being seriously used.

If the growth of the social sciences parallels at all that of the physical sciences, they will study in detail various systems, which, although of peripheral mathematical interest, are of substantive interest. Indeed, some examples already exist, including these: (1) Just as classes of maximum and minimum problems have been formulated and solved in the physical sciences, other classes have arisen in the social sciences, such as linear, nonlinear, and dynamic programming, game theory, and statistical decision theory. (2) Various mathematical structures that may correspond to (parts of) empirical structures have been investigated, for example, aspects of the theory of relations and the closely related theory of graphs, matrix algebra, and concatenation algebras, which arose in the study of grammar and syntax. (3) Underlying the

success of much physical theory is the fact that many variables can be represented numerically. The theories that account for this in physics are not suitable for the social sciences, but alternative possibilities are under active development, particularly in terms of theories of fundamental and derived measurement. The mathematics is reasonably involved, although for the most part the proofs are self-contained. (4) Although the theory of stochastic processes is a well-developed part of probability theory, a number of the processes that have found applications in the social sciences had not previously been studied by probabilists; their properties have been partially worked out in the social science literature. Among the most prominent examples are the nonstationary processes that have arisen in learning theory. Some of these postulate that on each trial one of several operators Q_i transforms a response probability into the corresponding probability on the next trial. Two special cases have been most adequately studied. One assumes that the Q_i are linear operators and the other assumes that the operators commute with one another—that is, $Q_i Q_j = Q_j Q_i$. [See LEARNING.]

As increasing use is made of mathematics in the social sciences, one may anticipate the investigation of very specific mathematical systems and, ultimately, the isolation of interesting abstract properties from these systems for further study and generalization as pure mathematics.

MAURRAS, CHARLES

Charles Marie Photius Maurras (1868–1952), French man of letters, was born in Martigues, near Marseille. He entered public life supporting both Frédéric Mistral's *Felibrige* and Jean Moréas, with whom he joined in 1891 in founding the *École Romane*, a literary movement designed to defend "a common ideal of Romanity." He became the apostle of integral nationalism, having coined the term in 1900.

Reacting against the dominant relativism and eclecticism of his time, Maurras set out from skeptical and agnostic premises to find some solid basis for thought, style, and action in historical realities which, he argued, having worked in the past, might be expected to work again. He rediscovered the classical ideals of order, hierarchy, and discipline

and insisted that they alone provide an escape from nihilism into the positive realm of "organizing empiricism"—a method of solving current problems in terms of past experience.

Transferred from literary to sociopolitical grounds, Maurras's *empirisme organisateur* turned him against what he considered the dissolvent and anarchic qualities of liberal individualism which had triumphed in the French Revolution. He thought France was in a state of decadence and attributed this to its abandonment of traditions identified with the old regime, campaigning against Protestants, Jews, and metics—all those alien agents of change and corruption to whom the revolution had given free rein in France. When, in the late 1890s, the scandals that periodically shook the Third Republic culminated in the Dreyfus affair, Maurras set out to elaborate a doctrine which might spark a reaction against the existing disorder and provide the basis of a national revival. Based upon penetrating if frequently unhistorical criticism of the republic and parliament, his critique asserted the necessity of a return to the historical sources of French intellectual and political success: the classical tradition of the seventeenth century and the monarchy. True patriotism, conscious of these conditions of national prosperity and greatness, demanded, he believed, a return to the stability and continuity which only hereditary monarchy could provide. This was the program of integral nationalism to which he soon converted the founders of the Ligue d'Action Française, a young, pragmatic, and patriotic movement dedicated to France's political and intellectual regeneration. Henceforth, the story of Maurras was that of the Action Française; he became its moving spirit, and most of his writings were published in the review (1899–1914) and the newspaper (1908–1944) of that name.

Despite his insistence that politics must take precedence over everything else (*Politique d'abord!*), the Action Française was less a political than a didactic and literary movement. The doctrine it taught combined traditionalism, regionalism, and corporatism and elaborated the picture of a society that was free of democratic sham, individualistic anarchy, and the struggles of political parties and that was ruled in a stable way by a monarch and by an elite of talent and birth who would consider only the interests of the nation, not those of particular interest groups. The negative aspects of Maurrasist doctrine were more convincing than its program, and its criticism of the republic and its institutions provided rich ammunition for all other critics. When written into legislation at Vichy

(particularly in 1940–1941), Maurras's views proved anachronistic and unworkable.

Nevertheless, the Action Française provided an intellectual structure to which the French right could refer; Maurras's doctrine synthesized the ideas of nineteenth-century conservatives from Bonald to La Tour du Pin and influenced several generations of France's middle and upper classes. Its newspaper never ceased to warn against Germany, against a Red peril—not so much a peril of social revolution as of national disunity—against the popular front of 1936, and, thereafter, against war and warmongers—at a time of national division and unpreparedness to which its own campaigns had contributed a good deal. A steadfast supporter of Philippe Pétain after 1940, though as steadfastly anticollaborationist (his ideas inspired much of Vichy's nationalist isolationism), Maurras was condemned in 1945 to life imprisonment. In prison, as out, his pugnacity and the stream of his writings never ceased. When his sentence was commuted in 1952 to forced residence in a private clinic, Maurras publicly thanked President Vincent Auriol, congratulating him for finally granting him the freedom that was his due and suggesting the expiatory execution of the minister "responsible for the excesses committed at the Liberation." He died a few months later, still bellicose but reconciled with the church he had abandoned as a youth.

Maurras's destructive effect on the democratic and parliamentary ideology has been immense, his constructive influence slight. Yet his ideas affected the nationalists of all Latin nations, and there are strong traces of Maurrasism in Salazar's Portugal and de Gaulle's France. The Action Française has been and still is well represented in the Académie Française (in 1964, by three of its leaders), and many still respect its ideas in the breach if not in the observance. Still, the movement Maurras led is now but a memory and a sect. Responsible for much of its success between the wars, Maurras also bears the responsibility for its eventual failure. His intellectual elitism made for overemphasis of the written word, and his authoritarianism brought him into conflict with the Roman Catholic church he professed to admire (not for its Christianity but for its enduring power) and with the royalty he professed to serve (less out of personal loyalty than for theoretical reasons). The deafness which rid him at an early age of faith in God or nature grew steadily worse, isolating him and encouraging his pessimistic and intolerant dogmatism. Younger followers deserted, were excommunicated, or simply drifted away. But this very dogmatism gave him

the strength needed to repeat tirelessly and to elaborate endlessly ideas which have left their mark on France and on the Latin world.

MAUSS, MARCEL

Marcel Mauss (1872–1950), French sociologist, was born in Épinal (Vosges) in Lorraine, where he grew up within a close-knit, pious, and orthodox Jewish family. Émile Durkheim was his uncle. By the age of 18 Mauss had reacted against the Jewish faith; he was never a religious man. He studied philosophy under Durkheim's supervision at Bordeaux; Durkheim took endless trouble in guiding his nephew's studies and even chose subjects for his own lectures that would be most useful to Mauss. Thus Mauss was initially a philosopher (like most of the early Durkheimians), and his conception of philosophy was influenced above all by Durkheim himself, for whom he always retained the utmost admiration; by Kant, to whose work Durkheim introduced him; and by two philosophers at Bordeaux, O. Hamelin, a rationalist, and the more empirically minded A. Espinas, then concerned with the collective origin of arts, customs, and technology—subjects about which Mauss was later to write. The philosophical atmosphere was Neo-Kantian. Mauss placed third in the national *agrégation* competition of 1895 and decided to devote himself to research.

He studied the history of religion at the École Pratique des Hautes Études under Louis Finot, Sylvain Lévi, Auguste Carrière, and A. Meillet in the Section des Sciences Historiques et Philologiques and under Alfred Foucher, Israël Lévi, and Léon Marillier in the Section des Sciences Religieuses. Meillet and Lévi, together with Célestin Bouglé, were among his closest friends. In 1897–1898 he made a study tour to Leiden, Breda, and Oxford, where he worked with Tylor. He then studied Sanskrit and Indian texts and, as Foucher's assistant from 1900 to 1902, taught the history of the religion and philosophy of pre-Buddhist India, in 1901 succeeding Marillier to the chair in the history of the religion of "noncivilized" peoples, which he occupied for the rest of his career. He taught, in addition, at the Collège de France from 1930 to 1939. In 1925 he helped to found, and then became joint director of, the Institut d'Ethnologie de l'Université de Paris, which, by virtue of the instruction it provided and the publications it sponsored, contributed considerably to the development of field work by younger anthropologists. Mauss lectured at the Institut on ethnography until 1939, encouraging field workers to "take trouble to be exact, complete" and to have a sense for "facts and the relations between them," for "proportions and connexions" (1947, p. 5). (Apart from a brief voyage to Morocco, Mauss himself did no field work.)

Mauss worked very closely with Durkheim. In addition to their major joint work, "De quelques formes primitives de classification" (Durkheim & Mauss 1903), he compiled statistical tables for Durkheim's study of suicide, and they collaborated in writing reviews. It was, on the whole, Mauss who, with his greater sense of the concrete, had an eye for the illuminating fact, while the theoretical interpretation generally originated with Durkheim. The notion of "total social facts," commonly attributed to Mauss (Lévi-Strauss [1950] 1960, pp. xxiv ff.), was, according to Georges Davy (1958), born of their collaboration arising from the study of some documents of Boas and was subsequently applied by Mauss. It is indicative of the cooperative nature of the work done by the brilliant young scholars whom Durkheim had assembled around the journal *Année sociologique* (published in 12 volumes between 1898 and 1913) that almost all of Mauss's major work in this period was written in collaboration: with Hubert he published "Essai sur la nature et la fonction du sacrifice" in 1899, "Esquisse d'une théorie générale de la magie" in 1904, and "Introduction à l'analyse de quelques phénomènes religieux" in 1908; with Beuchat he

published "Essai sur les variations saisonnières des sociétés eskimos" in 1906; and with Fauconnet he published an important encyclopedia article on sociology in 1901.

Mauss also took a major part in editing the *Année* from the time of its foundation, directing the religious sociology section with Hubert, collaborating on several other sections, and contributing a vast number of reviews and notes, to which he rightly attached great importance. World War I tragically decimated the *Année sociologique* group, and, after Durkheim's own early death, Mauss inherited the leadership of the group. He twice revived the journal (in the 1920s and in the 1930s) and devoted much of his time to editing posthumously published works by Durkheim, R. Hertz, Hubert, and others, thereby reducing his own output.

Mauss's most important post-World War I writings may be divided into two broad categories. First, there are the major ethnological studies: the great *Essai sur le don* of 1925, "Effet physique chez l'individu de l'idée de mort suggérée par la collectivité (Australie, Nouvelle-Zélande)" of 1926, "Les techniques du corps" of 1936, and "Une catégorie de l'esprit humain: La notion de personne, celle de 'moi'" of 1938. Second, there are writings of a methodological and programmatic character on the social sciences: "Rapports réels et pratiques de la psychologie et de la sociologie," which was a presidential address to the Société de Psychologie in 1924, "Divisions et proportions des divisions de la sociologie" of 1927, and "Fragment d'un plan de sociologie générale descriptive" of 1934. In addition, Mauss published other brief studies on a variety of subjects, among them the origins of the notion of money, the Melanesian potlatch, contract among the Thracians, joking relationships, the "Legend of Abraham," forms of civilization, social cohesion in polysegmentary societies, technology, the problem of nationality, and the sociology of Bolshevism.

Mauss also led an active political life. Like Durkheim, he supported Dreyfus and Zola, and he was a leading member of the Dreyfusard Groupe des Étudiants Collectivistes. He was closely associated with the socialist leaders, in 1904 helping them to found *L'humanité*, to which he contributed, taking part in strikes and supporting socialist candidates in elections. He was also much involved in the "popular universities" and the cooperative movements. The evolutionary, pluralist, and liberal quality of his socialism, akin to that of Jaurès, can be seen in the "Conclusions" to *The Gift* ([1925] 1954, pp. 63-81), where he stressed both the loss in terms of the quality of human relationships that

occurs when exchange becomes purely economic and the need to restore the older themes of "freedom and obligation in the gift, of generosity and self-interest in giving" (*ibid.*, p. 66).

Although Mauss is chiefly known as an ethnologist and historian of religion, he was in fact a polymath, one of the last encyclopedic minds, and had an extraordinary range of ethnographic and linguistic knowledge (his pupils said "Mauss knows everything"). Lévy-Bruhl (1951, p. 4) described his conversation and lectures as full of "new and fruitful ideas of which others made theses and books." His career was brutally ended by the German occupation, which for a second time deprived him of friends and colleagues and affected the balance of his mind. He never completed projected books on money, prayer (but see Mauss 1909), and the nation (the manuscripts of which were probably destroyed), and he never synthesized his many-sided and scattered work.

Contributions to theory. Mauss's theoretical contributions derive mainly from his concrete application and refinement of Durkheim's precept, "The essential thing is to unite not many facts, but facts at once typical and well-studied," as well as the precept laid down in the article written with Fauconnet (which was a sort of Durkheimian charter) that the sociologist must connect "collective representations" (i.e., collective ways of acting and thinking) with features of the social structure or with one another (1901, p. 172).

Thus the study of the Eskimos explores the relations between morphological factors, on the one hand, and legal and moral systems, domestic economy, and religious life on the other. Mauss related the crowded conditions in which the Eskimos lived in the winter to the development among them of a real community of ideas, to "a strong religious and moral unity of mind," which he contrasted with the social atomization, the extreme "moral and religious impoverishment" that accompanied the dispersal in summer ([1906] 1960, p. 470). Similarly, the classic study with Durkheim of primitive classification attempts to find the origin of classifications (such as space, time, hierarchy, number, class, etc.) in the social structure by establishing formal correspondences between social and symbolic classifications among Australian aborigines, among the Zuni, and in traditional China: thus "even ideas so abstract as those of time and space are, at each point in their history, closely connected with the corresponding social organization" (Durkheim & Mauss [1903] 1963, p. 88). The elucidation of these formal correspondences is of considerable theoretical interest and suggestiveness, however

questionable may be the causal chain that is postulated, the causal role given to affectivity, and the differentiation of cognitive operations from the content of thought (see Needham 1963). It was the first sociological study of classification and opened up the question, still immensely fruitful, of the relationship between symbolic classification and social structure.

Other examples of Mauss's practice of Durkheimian precepts are the study of magic, analyzed as a social phenomenon and defined as "*every rite which does not form part of an organised cult,*" being "private, secret, mysterious and tending at the margin towards the forbidden rite" (Hubert & Mauss [1904] 1960, p. 16); the study of sacrifice, analyzed as "a means of communication between the sacred and profane worlds, through the mediation of a victim, that is, of a thing that in the course of the ceremony is destroyed" (Hubert & Mauss [1899] 1964, p. 97); the study of the concept of the self, offering no more than a sketch of "the series of forms which this concept has assumed in the life of men in societies, according to their systems of law, their religions, their customs, their social structures and their modes of thought" (Mauss [1938] 1960, p. 335); and the studies of the social determinants of mourning rites (Mauss 1921), of the lust to die, and of uses of the body.

It is, however, *The Gift* that must rank as Mauss's masterpiece. It is the supreme example of the study of "total social facts," being concerned with a limited range of social phenomena seen as a totality, with "wholes, with systems in their entirety" ([1925] 1954, p. 77), namely, "prestations," or systems of exchange, which are "in theory voluntary, disinterested and spontaneous, but are in fact obligatory and interested" (*ibid.*, p. 1). He focused on a comparative study of forms of contract and exchange in Polynesia, Melanesia, and northwest America, with supplementary reference to evidence from early Roman, Hindu, and Germanic literature. The central hypotheses of the study are that "the archaic form of exchange," with its three obligations of giving, receiving, and repaying, is an aspect of almost all societies (and should be resurrected in our own), that it maintains and strengthens social bonds (cooperative, competitive, and antagonistic), and that by studying it concretely in its totality in the societies chosen, "we have been able to see their essence, their operation and their living aspect, and to catch the fleeting moment when the society and its members take emotional stock of themselves and their situation as regards others" (*ibid.*, pp. 77-78). Gift exchange is revealed as at once religious, legal, moral, economic, aesthetic, morphological, and mythological in significance;

the obligations it involves are symbolically expressed in myth and imagery and take the form of an interest in the objects exchanged, but these objects "are never completely separated from the men who exchange them; the communion and alliance they establish are well-nigh indissoluble. The lasting influence of the objects exchanged is a direct expression of the manner in which sub-groups within segmentary societies of an archaic type are constantly embroiled with and feel themselves in debt to each other" (*ibid.*, p. 31). Apart from its considerable ethnographic interest, *The Gift* was the first systematic and comparative study of gift exchange and the first elaboration of the relation between patterns of exchange and the social structure.

In general, it may be said that Mauss's theoretical contributions result from putting Durkheimian sociology to work, de-emphasizing its least acceptable features (the latent mysticism of the group, the crowd psychology, the identification of historical origin and analytical simplicity) and demonstrating its considerable explanatory power.

Influence. Mauss's influence is particularly difficult to measure because of his deep involvement in collaborative work with Durkheim and others. He was the Durkheimians' ethnographic adviser, and his part in the studies of magic, social morphology (1906), and primitive classification was of crucial importance in the development of Durkheim's own sociology of religion and knowledge. One may likewise assert, but not measure, his influence on other Durkheimians (such as Marcel Granet) and upon those who came under their collective influence, including historians (such as Lucien Febvre and Marc Bloch) and psychologists (such as Charles Blondel).

He had a direct influence, however, on French ethnology, inspiring such figures as A. Métraux, M. Leenhardt, M. Griaule, G. Dumézil, R. Bastide, and L. Dumont. He has been a major influence on Lévi-Strauss, who has written about him in terms which overstate Mauss's theoretical divergence from Durkheim (Lévi-Strauss 1945, 1950). Lévi-Strauss values above all Mauss's method, best illustrated in *The Gift*, of treating a total social fact as a symbolic system to be deciphered. Lévi-Strauss sees this approach as "inaugurating a new era for the social sciences" ([1950] 1960, p. xxxv), for it may be generalized to the whole of social life. Thus social life may be understood as a system of transactions between groups and between individuals, the rationale of which can be established by techniques analogous to those of structural linguistics. According to Lévi-Strauss, it is the great misfortune of modern ethnology that Mauss did not exploit his

discovery; he himself applied it in his theory of the exchange basis of cross-cousin marriage, which, he maintains, shows that in the field of kinship "the analogy with language, so strongly affirmed by Mauss, has permitted the discovery of precise rules, according to which there are formed, in any society whatever, cycles of reciprocity, whose mechanical laws are thenceforth known, permitting the use of deductive reasoning and offering the promise of a vast science of communication of which anthropology will be a part" ([1950] 1960, p. xxxvi). Leacock (1954) sees Mauss's work as more old-fashioned, condemning particularly its sociologism and evolutionism.

The Gift is Mauss's best-known work outside France, and indeed it is the only one that has made any impact in the United States; its theoretical suggestiveness seems by no means spent. Also influential have been the seminal studies of magic, sacrifice, and, increasingly, primitive classification. Mauss's influence is especially hard to identify in these areas because his work has entered into the common theoretical inheritance, often operating through the medium of colleagues and disciples. He appears particularly to have influenced the following anthropologists: A. R. Radcliffe-Brown, B. Malinowski (both of whom in different ways distorted his somewhat refined Durkheimianism), E. E. Evans-Pritchard, R. Firth, M. J. Herskovits, W. Lloyd Warner, and R. Redfield, among others. More generally, his influence is especially apparent in the anthropological work emanating from Oxford (via Evans-Pritchard) and in the work of the Leiden school (especially F. D. E. van Ossenbruggen and J. P. B. de Josselin de Jong). But the rich possibilities of his work have still to be fully exploited.

MAYO, ELTON

While the published writings of Elton Mayo (1880-1949) now seem to be mainly of historical interest, he personally had an enormous influence in the development of industrial sociology and psychology and in the stimulation of men who have made major contributions to research and theory.

Mayo was particularly influenced by the writings of the psychologist Pierre Janet. He combined an interest in psychoneuroses and what he termed "obsessive thinking," derived from his study of Janet, with the approach to culture and social structure of the social anthropologists Bronislaw Malinowski and A. R. Radcliffe-Brown. In research methods he adapted the interviewing methods of the clinical psychologists to the field methods of the anthropologists and brought them to bear on studies of industrial organizations.

Mayo was born in Adelaide, Australia, the second of seven children. He came from a family of professional men. In the process of finding his vocation, Mayo ranged widely in space and experience: from medical student to newspaperman to laborer to businessman, from Scotland to west Africa and back to Australia. From the printing business, he turned to the study of psychology at Adelaide Uni-

versity. A psychiatric treatment program he and a collaborator organized toward the end of World War I to deal with soldiers suffering from shell shock led to his appointment in 1919 to the newly established chair of philosophy at the University of Queensland.

Rockefeller and Carnegie foundation grants brought him to the United States and supported his first research in human relations in industry, which he began while at the University of Pennsylvania. The site of his first research in this field was a textile mill.

The most productive period of his life began in 1926, when he accepted a position at Harvard University's Graduate School of Business Administration. In association with Lawrence J. Henderson, an eminent biological chemist and devotee of Pareto, Mayo organized a research team to study the psychological and social problems of industrial workers. The aim from the beginning was to follow these problems wherever they led, without regard to customary disciplinary boundaries.

In 1927 Mayo launched the now famous Western Electric research program. He worked particularly with Fritz J. Roethlisberger, William J. Dickson, and T. North Whitehead, and it was they who produced the principal research reports of the studies carried on at the Hawthorne Works in Chicago. As director of the program, Mayo had the task of handling the diplomacy involved in making such an unprecedented research effort acceptable within a company, and he also made important contributions to the design of the research program and to the interpretation of the results (see *Management and the Worker* by Roethlisberger & Dickson 1939).

While Mayo was primarily interested in problems of individual adjustment, he recognized the necessity of examining such individual problems in the context of organizations and social structure. He was instrumental in bringing W. Lloyd Warner to Harvard and worked closely with him in launching the Yankee City study. At the same time, Warner became consultant to the Western Electric research program and there stimulated the analysis of problems of group and organizational structure.

In all his writings Mayo was concerned with two basic ideas, one dealing with the nature of society, the other dealing with the problems of individuals. He argued that the industrial revolution had destroyed traditional society in which people responded to each other in terms of established routines. The breakdown in these traditional understandings had led to widespread conflict in industry and society. The traditions of old could not

be re-established, and, therefore, the only solution must be to build an adaptive society in which an administrative elite, trained in social understandings and skills, would resolve human as well as technical problems.

He saw workers suffering from a form of anomie, the failure to find a satisfactory place for themselves in the world of work, with a consequent involvement in obsessive reveries in which they brooded unproductively over their problems. For dealing with these problems of obsessive thinking, he had great faith in the therapeutic relationship in which the individual is encouraged to talk out his problems freely to an interested listener.

Although Mayo directed the Western Electric research program, the principal research fruits of that program bear little relation to Mayo's ideas about social integration, obsessive thinking, and psychotherapy. To be sure, *Management and the Worker* does devote chapters to the personnel-counseling program, a direct outgrowth of Mayo's ideas, but that program was later abandoned by the company and never served as a model for other companies. Furthermore, few research men today consider a personnel-counseling program of much importance in dealing with problems of human adjustment in industry. The principal fruits of the Western Electric studies are found in those parts of *Management and the Worker* which deal with informal relations among workers, with worker-management relations, and with the methods for gathering systematic observational and interviewing data upon behavior in organizations. These contributions provided the foundation for the very rapid development of research on organizational behavior in the two decades following publication of that book in 1939.

Mayo, as the father of research on the human problems of industry, also became the principal target for attack. Critics argued that there was no place in his philosophy for conflict, that he sought to achieve organizational harmony through the subordination of individual and group interests by the administrative elite, and that he did not understand the role of unions in a free society. Mayo's supporters replied that he had no illusions about the possibility of establishing perfect harmony in any industrial society. He simply observed that there is so much destructive conflict that it is well to seek better ways of handling human problems. While Mayo has been charged with being anti-union, it might be more accurate to say that he was simply indifferent to unions. In his most productive period of work with Western Electric, the company had only a weak company union. Al-

though unions had become a prominent part of the industrial scene long before Mayo's death, he did not think they fundamentally altered those human problems of industry that interested him, and he never integrated unions into his thinking about industry.

Mayo was not a systematic theoretician. He had a wide-ranging mind and creative social abilities. Few men have contributed as much as he to the establishment of new fields of social research and teaching. He was a behavioral scientist long before the term became popular.

MEAD, GEORGE HERBERT

The work of George Herbert Mead (1863-1931), one of the leading figures in pragmatism, has had a profound impact on the development of American social science. Despite the lavish praise of Dewey and Whitehead, most philosophers tended to neglect him, because his ideas were not readily accessible during his lifetime. He was reluctant to set down in writing views that were still being

formed; he published no books, and many of his articles dealt with education, psychology, and sociology. Communicating most effectively in oral discourse, Mead developed his thoughts in extemporaneous lectures at the University of Chicago, where he taught from 1893 to the time of his death. Although his style was involved and labored and even his admirers acknowledged difficulties in deciphering his sentences, the classes were well-attended; and his influence upon colleagues and students, especially in sociology and social psychology, is readily discernible in their writings. Four posthumous volumes have been pieced together by devoted students from stenographic notes of his lectures, fragmentary manuscripts, and tentative drafts.

Pragmatism represents an attempt to reformulate conceptions of man and his place in the universe in terms of the revolutionary implications of scientific method and of evolutionary theory. Mead viewed evolution as the process of meeting and solving problems and scientific method as the evolutionary process grown self-conscious. The characteristics of various species develop as organisms come to terms with life conditions, and Mead wanted to account for the emergent properties of man—thinking in abstractions, self-consciousness, and purposive and moral conduct. He contended that these attributes rest on the development of language, a form of social interaction that evolves among human beings as they meet the exigencies of living in groups.

Thus, Mead's central hypothesis made social psychology basic to his philosophical work. His approach was behavioristic, although not in the narrow sense of John B. Watson: man is to be studied in terms of his deeds, covert as well as overt. Since, however, each person is involved in a succession of joint enterprises with others, his acts can best be regarded as segments of larger transactions. Social psychology is the study of regularities in individual behavior that develop from participating in groups. Mead also stressed the temporal dimension—the extension of individual and group activities over time.

Analysis of the "act"

Society is an ongoing process and consists of social acts. By *social act* Mead meant a transaction involving two or more persons among whom there is a division of labor. The contributions of various individuals are coordinated to achieve objectives that bring gratifications of some sort to each. Unlike the instinctive cooperation found among social insects, concerted action among human beings is characterized by a high degree of flexibility. The

participants build up a social act as they continuously adjust to one another and to the demands of the developing situation. Should there be drastic environmental change, entirely novel patterns may emerge. Such concurrence among separate and independently motivated individuals is made possible by *role taking*, the ability of each to visualize his own performance from the standpoint of the others. Each person is able to comprehend the entire transaction, locate himself within it, and regulate his own contributions to fit into the larger pattern. Coordination depends, then, on the self-control of each actor. In highly institutionalized transactions, collaboration is facilitated insofar as the participants share a common perspective; each of them takes the role of a *generalized other*.

The execution of a social act is a communicative process; transactions of all kinds develop in the reciprocating adjustments of the participants. Mutual orientation is built up and maintained in a continuous interchange of gestures. A *gesture* is any perceptible sound or movement which indicates to a second party the inner experiences or intentions of the first; any act may become a gesture when an observer responds to it in terms of what it represents. Speech, which consists of vocal gestures, is of special importance. Since a speaker is able to hear his own remarks in much the same manner as his audience, the establishment of mutual understanding becomes easier. A gesture that has the same meaning for two or more people is a *significant symbol*, and language consists of such conventional sounds. Those who are associated in common activities eventually develop a universe of discourse, which facilitates their subsequent collaboration.

Although each deed is a fragment of a larger social act, it is also an episode in the life of an individual. Mead's basic unit of analysis is the *act*, which is initiated by some want and is directed toward its satisfaction through the use of suitable elements of the environment. All behavior can be broken down, for purposes of analysis, into a series of acts. Each act has a history; it is constructed as an organism makes a succession of adjustments to conditions (external and internal) that are undergoing constant change. Overt behavior is usually only the final phase of an act; in most cases it is preceded by a number of preparatory adjustments, including various subjective experiences. An act is teleological, it is not a mere sequence of passing events but an organized whole directed toward an end. To study such processes Mead proposed the concepts of impulse, perception, manipulation, and consummation. An *impulse* is a disturbance, any lack of adjustment between the organism and its

milieu—pique over an imagined slight, hunger pangs, or concern over a difficult task to be faced. *Consummation* is the elimination of the disturbance. In his study of motivation, then, Mead developed an approach resembling some of the more recent tension-reduction models. His scheme was comprehensive, and his concepts made it possible to show the relationship between organic needs, external stimulation, conscious intent, and overt movements.

Between the terminal points of the act lie *perception* and *manipulation*; it is through these processes that various features of the environment become involved in the act. An organism is in continuous interaction with its milieu, and activity is redirected in response to a succession of sensory cues. Perception is selective: not everything in the environment is noticed. An *object* is something that is essential to the completion of the act, and a person is sensitized to whatever will enable him to carry out activity that is already under way. Both perception and manipulation rest upon hypotheses. An object is approached in terms of expectations: a person anticipates what would happen if he were to move forward and touch it. For this reason Mead referred to perception as a "collapsed" or "telescoped" act. What is perceived depends in part upon what is anticipated; these hypotheses are then tested and confirmed in manipulation, the handling of objects as tools.

The hypotheses upon which perception and manipulation rest are derived from the meanings of objects. For pragmatists *meaning* is primarily a property of behavior and only secondarily a property of the objects themselves. Meanings are stable relationships between an organism and a class of objects, defined in the manner in which the latter are characteristically handled. Physical attributes are important because they set limitations upon what can be done. Most meanings are subject to social control in that the anticipated reactions of other people place additional restrictions on usage. Approaching sacred objects without sufficient deference, for example, elicits outraged protests. Such expectations are incorporated into the organization of the act. Members of each species select out of their environment objects that are essential to their survival and organize responses toward them; the world view of human beings is necessarily anthropomorphic and social. But pragmatism is not solipsistic. Reality is objectified through activity, but the orientations which support such activity are subject to reality testing. Hypotheses that turn out to be unreliable are rejected, and objects are redefined.

Once an act is under way, it generally proceeds

to consummation. One of the major contentions of pragmatists is that *thinking* is a form of behavior that occurs when activity is interrupted. The interference may arise from an external barrier, a disability of the organism, or an absence of necessary objects. When an act is blocked, a number of secondary adjustments take place, including emergency mobilization (emotion) and conscious reflection; and through these processes a delayed act may eventually be completed. Any impulse that is not immediately consummated is transformed into an *image*, which serves as the basis for reflection. Images are acts that fail to issue in overt behavior, acts that are innervated but not carried out. Each image may be regarded as a plan of action, one possible way of completing the interrupted act. A perplexed individual experiences a succession of images, and reflective thought is an imaginative rehearsal—a comparison and evaluation of alternative routes to consummation. Mentality may be regarded as the ability to anticipate the consequences of projected lines of action and to respond to them prior to commitment to overt action. Thinking, then, is problem-solving activity in which trial and error takes place in the imagination.

Once a person has mastered a language, images and objects may be designated by symbols; alternative plans of action are labeled, and their consequences are examined verbally. *Consciousness* is inner discourse, subvocal linguistic communication. While thinking is a private experience, it takes place through significant symbols; it is therefore behavior organized from the standpoint of a generalized other. The use of language transforms the effective environment to which human beings adjust. By using words, one can manipulate meanings outside the contexts in which they have developed and even make up more complex meanings. Foresight and planning are greatly facilitated. With symbols one can isolate certain experiences and hold on to them, pick out other relevant meanings, or emphasize a particular image while rejecting others. Language also makes possible the formulation of complex plans, broad schemes in which diverse and even antagonistic tendencies may be coordinated and a sequence of operations performed. *Mind* for Mead was internal symbolic communication, and it is this type of cognitive activity that computer engineers are now attempting to reconstruct. Modern decision theory describes regularities in the selection process.

Analysis of the "self"

Mead is best known for his theory of the *self*. The self is not one's body but a perceptual object. Since most acts are components of larger trans-

actions, the actors are interdependent; the impulses of one cannot be consummated without the cooperation of his associates. Each participant therefore becomes concerned over the possible reactions of the others to himself, for he cannot afford to do anything that will jeopardize their support. Each person forms an object of himself through role taking, by reviewing his intended conduct from the standpoint of those with whom he is involved in a common venture. Mead's discussion was rendered unnecessarily difficult by his use of the term "self" to designate three different referents: (1) the perceptual object formed of oneself in a particular historical context, (2) the process of self-control, and (3) one's personality.

Voluntary conduct is constructed in a sequence of adjustments in which a person responds to himself as well as to the rest of his perceptual field. To study this process Mead proposed the concepts of the *I* and the *Me*; these terms refer not to agents but to phases of activity. The "*Me*" is the object one forms of oneself from a conventional standpoint, and the "*I*" is the reaction of the unique individual to the historical situation as he perceives it. Typical inclinations to react differ from person to person; in fact, the succession of "*I*'s" constitutes the basis of individuality. In speaking of behavior as being built up in the interaction of the "*I*" and the "*Me*," Mead was stressing the seriated character of human conduct. If an impulse (*I*) is not immediately carried out, it is transformed into an image (*Me*), which in turn elicits another reaction (*I*). For example, if a man believes that his wife is disparaging his efforts (*Me*), he may want to beat her (*I*). As he refrains from striking, he imagines himself administering the beating (*Me*). Since he views himself from the standpoint of a group in which wife beaters are condemned, he reacts with disgust (*I*), and this inhibits one route to consummation. Frustrated and hurt (*Me*), he reacts with determination to demonstrate his competence through a superlative performance (*I*). Thus, an individual's line of conduct is constructed as he adjusts to a succession of organic states, perceptual objects, images, and anticipated reactions of other people. Self-control is part of the ongoing social current; each person adjusts in advance to the situation in which he is involved and thereby facilitates cooperation. In this process self-consciousness provides the basis for corrective measures. For Mead, as for Norbert Wiener, autonomy depends upon feedback; without it one becomes a creature of impulse or is subject to drift or external control. A crucial feature of feedback in self-control is that the object is formed from a standpoint shared with other people. The

fact that all participants control themselves from the same perspective (generalized other) makes concerted action possible.

A human being is not born with a mind and self-discipline; these capacities develop gradually as the child comes to terms with the demands of group life. The meanings of objects and gestures are products of experience; appropriate ways of handling things and of speaking are shaped largely by the consistent responses of elders, who provide instructions, serve as models, and reinforce the accepted modes of conduct. Mead emphasized two especially important contexts for socialization. In *play* young children assume specific roles and imitate individuals they know—mother, postman, salesclerk. In so doing they begin to appreciate the perspectives of others. By repeating such role taking the child is able to build up an orientation toward himself as an object of a certain sort. But effective self-control develops only in the *game*—or in any other enterprise that requires teamwork. In games the responses of others are organized, and activity proceeds according to rules. The contributions expected of each player are standardized into impersonal roles. Furthermore, successful participation requires the ability to assume multiple positions vis-à-vis oneself: one must be ready to take the role of any other player. Through repeated participation in such transactions, the child learns to adopt a point of view that is shared by all other participants (generalized other), a perspective that transcends that of particular individuals.

Although Mead saw human beings as inextricably involved in groups, he stressed the importance of individuality. Each person, although a product of society, retains his distinctiveness, for he incorporates the generalized other from a unique standpoint. As one develops the capacity for conscious communication, one achieves greater independence from others and greater discreteness as an individual. For each person self-realization is attained through the consummation of a distinct set of impulses; what brings fulfillment to one individual will not necessarily satisfy another. Furthermore, each person has a unique impact upon his community. Even when he is complying with conventional norms, he does so in his own style. The contributions of a genius are often striking and extensive and therefore more readily discernible, but everywhere allowances have to be made for the idiosyncrasies of the less talented. Thus, through self-assertion, each individual alters somewhat the social pattern in which he participates.

As a social philosopher Mead had a deep bias toward amelioration through understanding. The

son of a Congregationalist minister in Ohio, he may have been influenced by the climate of opinion of his community, a station of the Underground Railroad and locale of the first college to admit women. He believed that progress takes place through the constant meeting and solving of problems. Social institutions, like everything else in nature, are continually evolving, but men can direct this process through intelligent action. Scientific method provides the most efficient way of solving problems and should be used to facilitate human adaptation. The ideal society is one in which there is maximum participation by all members, one in which each person understands all the others and still retains his individuality. This ideal, while imperfectly realized, is constantly being approximated. Mead believed that history is on the side of progress and that eventually a brotherhood of man will emerge.

Since pragmatism is an application of scientific method to philosophical problems, it is not surprising that Mead's position is so much like the developing outlook of the natural and social sciences. Mead was a thinker who was ahead of his time. His views on matter, space, time, and relativity are similar to those of modern theoretical physics; and his discussion of meaning resembles P. W. Bridgman's work on operational definitions. Many of the ideas Mead developed at the turn of the century are now widely accepted in social psychology: the selective and seriated character of perception, cognition through linguistic symbols, role enactment, decision processes, autonomy through feedback, personal identity, reference groups, and socialization through participation. Because of the congruence of Mead's views with current trends, it seems likely that increasing attention will be directed to his work. Many implications of his position still remain to be explored.

I ETHNOMEDICINE

Judging from paleopathological evidence, diseases of one kind or another have always afflicted

man. Indeed, given the nature of life and the nature of disease, it could not be otherwise; for disease is but an expression of man's dynamic relationship with his environment. And even as there has always been sickness, accident, deformity, and anxiety to trouble man, so, too, has there been an organized, purposeful response by society to such threats. In all human groups, no matter how small or technologically primitive, there exists a body of belief about the nature of disease, its causation and cure, and its relations to other aspects of group life. There also exist therapeutic and preventive practices, many of which are empirically efficacious by standards of modern medicine, although often not for the reasons advanced by folk belief. The variability of societies and cultural systems impedes easy generalization about the nature of "primitive" or "folk" medicine (cf. Ackerknecht 1942a), but one common characteristic is its close integration with other institutions of the society. Religion, medicine, and morality are frequently found together in the behavioral act or event, and "folk medicine" becomes "social medicine" to an extent not found in industrialized societies.

The term "ethnomedicine" will be used to refer to those beliefs and practices relating to disease which are the products of indigenous cultural development and are not explicitly derived from the conceptual framework of modern medicine. In this light, most of the following discussion focuses on the non-Western, nonindustrialized societies of the world, although it is clear that in "modern" societies as well there exist beliefs and practices relating to disease and its treatment which are based on magical or religious conceptions rather than on those of scientific medicine.

Theory of disease. Man, everywhere, devises or divines causes for the significant events in his life. The afflictions which beset body and mind are explained in both naturalistic and supernaturalistic terms. A cut finger, a broken limb, a snake bite, a fever, the halting speech and wandering mind of senility—all may be regarded as sometime hazards in life. To explain such events there is always some conceptual framework founded in common-sense empiricism. But often a wound does not heal, a sickness does not respond to treatment, and the normally expected and predictable does not happen. In such cases another order of explanation is employed, one which attempts to come to terms with the more basic *meaning* of the event in metaphysical perspective. For most non-Western societies this transcendent explanation for the occurrence of disease tends to figure more pervasively in the total body of medical lore and practice than does

the empirical framework. One reason is the greater incapacitation and mortality from disease in the underdeveloped world than in highly industrialized societies. In addition, this reality is coupled with the comparative inadequacy of ethnomedical techniques and knowledge for dealing with these common threats to the existence of the group and the person.

Widespread throughout the world are five basic categories of events or situations which, in folk etiology, are believed responsible for illness: (1) sorcery; (2) breach of taboo; (3) intrusion of a disease object; (4) intrusion of a disease-causing spirit; and (5) loss of soul (Clements 1932). Not every society recognizes all five categories; indeed, many groups are selective in the emphasis placed upon one or a combination of causes. For example, the Eskimo most frequently trace the origin of diseases to soul loss and breach of taboo, while the malevolence of sorcerers or witches is especially emphasized in many African cultures. Usually, however, these categories are more useful in analytically characterizing the etiological beliefs of a particular group than in describing the content of an entire belief system. This would be the case where a disease is believed to be caused by the intrusion of an object which *contains* a spirit, and it is the latter to which primary causative influence is attributed (e.g., Hallowell 1935).

The Greeks were not alone in viewing disease as a manifestation of disharmony in man's over-all relation to the universe. "Health" is rarely, if ever, a narrowly restricted conception having its locus only in the well-being of the individual body. In discussing conceptions of illness among a west African people, Price-Williams gives a modern illustration:

In common with a great many other people, Tiv do not regard "illness" or "disease" as a completely separate category distinct from misfortunes to compound and farm, from relationship between kin, and from more complicated matters relating to the control of land. But it would be completely erroneous to say that Tiv are not able, in a cognitive sense, to recognize disease. As Bohannan has said: "The concept of a disease is not foreign to the Tiv: mumps, smallpox, . . . yaws and gonorrhoea are all common and each has a name." What is meant is that disease is seldom viewed in isolation. (1962, p. 125)

Such a notion is widely found, as in certain American Indian groups, where bodily or mental affliction is often viewed as an indicator of moral transgression, in thought or in deed, against the norms of society. Indeed, man is frequently thought of as continuous with both the social and nonsocial

aspects of his environment, and what happens in his surroundings affects his bodily well-being. Not only a person's own actions, therefore, but also those of kinsmen or neighbors can cause sickness. Such an etiological conception has obvious implications for treatment. For example, if the curative technique includes magically based dietary restrictions, they may apply to all members of the patient's family; a breach of the restriction by any of these people will undermine the patient's health. Similarly, as among the Thonga of South Africa, sexual relations between any of the inhabitants of the patient's village can aggravate his condition, and some Eskimo groups feel that the patient's family should do no work during the period of convalescence for fear of giving offense to the spirit causing the sickness.

The belief that by his own actions a man can influence the state of his fellow's health also has malevolent implications, as in the practice of witchcraft and sorcery. Frequently this may be an important factor deciding the success or failure of attempts at introducing new medical programs in underdeveloped societies. Cassel (1955) cites as an illustration the Zulu, who believe that only sorcerers and witches have the ability to transmit disease, particularly diseases which show themselves in symptoms normally associated with pulmonary tuberculosis. Progress in one community's acceptance of a Western-styled health program was brought to an abrupt halt when a physician tried to introduce the medical concept of contagion. He traced the course of tuberculosis through a family, showing how one person had been the original source of the disease in the group and had therefore been the agent responsible for sickness in all the others. The cautious cooperation of the family elder immediately turned into a hostile rejection, which was assuaged only after the doctor had retracted his apparent accusation that the daughter of the family was a witch.

A theory of disease implies a theory of normality. Yet the "normal" is in no way easy to define for all times and places. Aside from questions of a "statistical" versus a "functional" basis for normality, there is the cultural definition. Afflictions common enough in a group to be endemic, though they be clinical deformities, may often be accepted simply as part of man's natural condition. Ackerknecht (1946), for example, has noted that the Thonga believe intestinal worms, with which they are pervasively affected, to be necessary for digestion; the Mano, also of Africa, feel that primary and secondary yaws are so common that they say, "That is no sickness; everybody has that." North Ama-

zonian Indians, among whom dyschronic spirochetosis is prevalent, accept its endemicity to such an extent that its victims are thought to be normal, and individuals who have not had the disfiguring disease are said to be looked upon as pathological and consequently unable to contract marriage. It is culture, not nature, that defines disease, although it is usually culture and nature which foster disease.

Recent behavioral science research has attempted to go beyond a "phenomenological" orientation in investigation of cultural theories of disease and has sought analytic categories which would relate particular emphases in a theory of disease to other aspects of social and cultural life. A striking example of this type of investigation is the work of John Whiting and Irvin Child (1953). Using a wide sample from the ethnographic "laboratory," these investigators found high correlations between certain aspects of child-rearing practices and dominant themes in etiological beliefs related to disease, more particularly, between the hypothesized degree of anxiety generated during the socialization process—the degree of "negative fixation"—and a theory of disease which reflects these anxieties. Thus, harsh weaning is highly associated with oral explanations for onset of disease: these would include consumption of food, drink, or poison by the sick individual or oral activity on the part of others, such as incantations and spells. Societies in which independence training is characteristically fraught with emotional hazards tend also to have "dependence" explanations of illness. These include soul loss or spirit possession. "Aggression explanations" for disease are highly associated with societies in which training for handling aggressive impulses leaves a residue of unresolved anxiety, and they are expressed in theories which ascribe the cause of a disease to the patient's disobedience or aggression toward spirits, to aggressive wishes on the part of the patient or another person, to introduction of poison other than by mouth, or to harm by magical weapons or objects.

Theory and practice of treatment. Therapeutic practices in ethnomedicine address themselves to both supernatural and empirical theories of disease causation. Ackerknecht has said that primitive medicine is "magic medicine" (1942*b*); certainly much of it is, and, insofar as supernatural causes are involved, therapeutic regimes are based on countervailing supernatural powers or events. Thus, the powerful shaman or healer attempts to recover the soul lost or stolen by a human or supernatural agent. The intrusion of a disease object or disease-causing spirit is treated by extraction or exorcism,

and diseases which come as punishment for breach of taboo are usually treated by divination or confession of the infraction. Forgiveness and re-establishment of harmony with the moral and supernatural order are thus important outcomes of the therapy.

In folk medicine, however, there is more to treatment than magical or religious ritualization, however effective this may be psychosocially in providing emotional catharsis and reassurance. All human groups have a pharmacopoeia and at least rudimentary medical techniques; some groups, indeed, are exceptional in their exploitation of the environment for medicinal purposes and in the degree of their diagnostic and surgical skills (Ackerknecht 1942b; Sigerist 1951; Laughlin 1963). The trephining done by the Inca, Masai surgery, the anatomical knowledge of the Aleut and the Eskimo, and the extensive drug repertory of west African tribes are familiar examples. In addition to trephining, numerous other types of surgery and bonesetting are found, as well as massages, blood-letting, dry cupping, bathing, inoculation, and cauterization. It has been estimated that from 25 to 50 per cent of the non-Western pharmacopoeia is empirically effective. In fact, our knowledge of the therapeutic efficacy of a large number of modern drugs is derived from the experience of primitive peoples: opium, hashish, hemp, coca, cinchona, eucalyptus, sarsaparilla, acacia, kousso, copaiba, guaiac, jalap, podophyllin, quassia, and many of the tranquilizers and psychotomimetics now used in psychiatric therapy and research.

A great part of the task of folk medicine, however, and especially of preventive medicine, is borne by cultural practices which, although oriented to different social purposes, have important functional implications for health. Thus, notable hygienic purposes are served by many religious and magical practices, such as avoidance of the house in which a death has occurred, theories of contagious "bad body humors" which necessitate daily bathing, distinctions of "hot" and "cold" food and water which require boiling or cooking, hiding of fecal and other bodily waste through fear of their use by sorcerers or witches, and numerous others.

Other cultural practices inadvertently relevant to health have a more general ecological basis. These may include customs regarding cosmetics and clothing or house styles and settlement patterns. Regardless of their value to the archeologist, the middens of ancient sedentary communities have rather baleful implications for the public health of the times. Changing economic incentives and circumstances which disrupt the adaptation of a cultural activity to its environment frequently

create health hazards. May (1960) provides a striking illustration of the intersection between cultural and ecological factors in North Vietnam. Dwellers on the plains lived in low, squat houses in which they sheltered their cattle on one side and did their cooking on the other. When these rice growers moved into the hills they constructed houses according to the same general plan. In the hills, however, the incidence of malaria among them became so high as to limit further such movement, despite governmental encouragement. The people themselves ascribed the calamity to the ill will of the hill deities. In fact, however, the incidence of malaria was low among the indigenous hill people, who constructed their houses on stilts, sheltered their animals underneath, and did their cooking inside the house. Several factors were apparently instrumental in the latter case in keeping down the spread of malaria from the mosquito vector found in the hills; flight ceiling of *Anopheles minimus* is restricted to about ten feet above the ground, and, despite its preference for human blood, the presence of animals underneath the house and of smoke inside the house (where the cooking was done) created an unrealized protection for human inhabitants.

The study of folk medicine has important theoretical implications for the persistent question of a "magical" versus a "scientific" orientation among non-Western peoples. Erasmus (1952), utilizing data from South American Indian populations, contends that the inductive epistemological framework of folk medicine is essentially similar in structure to that of modern scientific medicine, but that the latter differs chiefly in its amenity to generalization and degree of predictive success. In folk medicine the chances of "natural" recovery are in favor of predictive successes, but, more often than in modern medicine, the theoretical propositions lying behind such predictions are merely coincidentally rather than functionally related to the phenomenon in question. Thus, the recocking, before eating, of food that has been left standing overnight is done on the basis of the need to dispel the dangerous quality of "coldness" in the food, but in fact such recocking destroys enterotoxin-producing staphylococci.

The possible implications for a sociology of knowledge are apparent: so long as any activity or set of activities produces a sufficiently high proportion of predictive successes, there will be little elaboration or alteration of the conceptual framework orienting the activity. Cognitive frameworks relating to disease are instruments in the total process of adaptation; they change, evolve, and respond when their viability and acceptability are

challenged. Only when folk etiology fails too often and in too many areas to give pragmatic and especially psychodynamic satisfaction does it yield to other frameworks, autochthonous or adopted from outside.

Disease, medicine, and culture. Some knowledge of diseases, their classification and etiology, is part of all cultural systems (e.g., Lieban 1962; Rubel 1960; Price-Williams 1962). Investigators have analyzed disease categories in an attempt to understand the structure of the conceptual world of different peoples. The use of componential analysis, the investigation of semantic interrelationships of terms, has been applied to words for sicknesses (cf. Frake 1961). Aside from illustrating the extent to which concern with disease is elaborated in a folk nosology, such work also emphasizes a more general point: an effective cultural response to disease requires patterned discrimination and categorization of disease symptoms, even if treatment is based largely on methods of trial and error. Diagnostic categories, however crude, serve the purpose of directing sustained attention and reflection to the appearance of disease syndromes, thus providing empirical data for inferences about the probable effectiveness of one type of treatment or another. Undoubtedly this constitutes a kind of inadvertent experimental approach (see, e.g., Laughlin 1963; Erasmus 1952).

Theories of disease generally have major relevance to the moral order, that is, to the control of man's behavior in society. Disease is frequently seen as a warning sign, a visitation from punishing agents for a broken taboo, a hostile impulse, or an aberrant urge to depart from the approved way. In a series of classical papers, Hallowell (e.g., 1963) has analyzed the function of anxieties over sickness among the Ojibwa Indians of North America, and other investigators have looked at the same problem in different cultural settings (e.g., Lieban 1962). Sickness is often interpreted as the supernaturalists' way of indicating an act or intention of socially disruptive behavior. Especially in societies lacking strong centralized sociopolitical institutions, the occurrence and imminence of disease—with the belief that it represents punishment for aberrant, dissocial impulse or action—can be functionally important in maintaining group cohesion and restraining disruptive tendencies.

The therapeutic practices attendant upon occurrence of disease may also have socially cohesive results. Although such therapy may often be medically effective, it may serve ancillary functions in the total organization of the society. Typically, the curative session (and often the diagnostic occasion as well) involves not only the patient and the

healer but also the patient's family and neighbors. Often the therapy involves confession by the patient, and under such conditions the confession may well relieve him of diffuse as well as focused anxieties and guilt. When followed by concrete expiatory acts, it may also give him a chance to participate in his own treatment through action. (It is doubtful whether such curative rites do more than provide temporary symptom relief—but the same can be said of much modern psychotherapy.) At the same time group cohesion is often enhanced, for such confessions dramatize fundamental social values by illustrating the harm that can come from social deviance. They provide a setting in which all participants are enveloped in the aura of forgiveness and, through stress on the protection afforded by adherence to group values, assurance of good health. In short, the therapeutic context is usually explicitly a social context, and during the course of the therapy the reciprocal psychosocial involvement of the patient with his fellows is ritually underscored. As noted above, if therapeutic directives for behavior are issued, they frequently apply to the group, or selected members of the group, as well as to the patient; and if successful recovery is as dependent upon good thoughts as upon effective techniques—as frequently happens—then the assembled company must be devoid of ill wishes and hostilities toward not only the patient but also each other. The curative rite may thus serve in multiple ways as an occasion for reintegration of the group around common social values.

The practice of folk medicine is variously institutionalized. In all societies some rudimentary medical knowledge is an aspect of enculturation, but beyond this general protection there is always a specialist. Sometimes the specialist's role is a full-time activity, but more frequently it is combined with other principal roles appropriate for the practitioner. In some societies there are more complex social arrangements than the simple dyadic relationship between healer and patient. Even as the kin and covillagers of the patient may be explicitly involved in the curative process, so too there may be a society of healers or several societies of healers devoted to diagnosis and cure of various diseases. In west Africa there are found, for example, specialized associations of healers of smallpox or snake bite; each association possesses its own rules of qualification, initiation, and procedure (Harley 1941).

Folk medicine in change. Folk medicine does not easily change under the impact of sustained contact with the industrialized world, or even as a result of deliberate attempts to introduce new conceptions of disease and hygiene. Paul (1955), Fos-

ter (1962), and others have documented the variety of factors that may impede or altogether prevent the successful introduction of a modern health program, even of so simple an innovation as the boiling of drinking water. Such factors include ecological considerations, as well as functional efficiency in domestic tasks, the social structure, the status and prestige of the innovator, and the perception of threat or advantage to the recipient. The proper role of the healer may be differently defined; in India, for example, the medical practitioner must assure the patient of recovery, and any admission of uncertainty (even couched in the form of probability) is not allowed. Rudimentary physical testing may be impossible or difficult in a non-Western context. In societies where blood, for example, is thought of as a nonregenerative substance, to take samples for testing is tantamount to inflicting deliberate harm.

It has been found to be easier to introduce behavioral changes than changes in belief about the nature of illness, its cause, and prevention. Domestic hygiene and community health may be bettered by the public health worker who influences a change in habits while not disturbing the underlying belief system. One reason for this has been mentioned above: belief systems, particularly those centered on critical areas of social value, serve more than a single cognitive function. Because they interrelate with religious and magical systems, as well as with the moral order of the society, they impart a deeper sense of resignation and acceptance of events than does an alien concept treating of a germ theory of illness. The value system of a culture provides a more satisfying answer to the question, "Why did I and not my neighbor get sick?" than does an explanation phrased in terms of communicability of a disease, thresholds of resistance, host, agent, and environment.

Yet in many instances modern medicine does get accepted; and one of the reasons is its demonstrably greater effectiveness in the treatment and prevention of many diseases. But even such acceptance is often compromised by the existence of alternative diagnostic and therapeutic frameworks: one relating to those diseases for which it is felt modern medicine is more effective, and the second relating to diseases conceived to be unamenable to modern medical treatment. The first is often applied to sicknesses introduced by the Europeans (such as tuberculosis, measles, smallpox, and others of a communicable nature), while in the second group are traditionally endemic diseases and, especially, ailments having a large component of psychological or psychophysiological involvement.

But in the extremity of fear for a patient's life even such distinctions as these are often disregarded, and the ill person may be taken to a modern medical facility after indigenous healers have done their best—taken either to be cured or left to die. Every hospital, and not just those in non-Western, "underdeveloped" countries, will admit patients brought too late for the course of disease to be halted even by the most advanced techniques of scientific medicine. Disease being an unequivocal threat to life, adaptive responses are many and sometimes override ingrained belief, either of folk medicine on the one hand or modern medicine on the other. In this light, given the avowedly limited role of scientific medicine in society—together with the inevitability of disease—elements of folk medicine will no doubt everywhere persist, even as they do in Europe and the United States, so long as there is uncertainty of outcome or technical ineffectiveness in alleviating pain, prolonging life, and guaranteeing cure.

II SOCIAL ASPECTS

Medical care is the application of scientific knowledge and technique to solving the physical and emotional problems of man. To a physician, medical care denotes the body of diagnostic and therapeutic theory and procedure developed to understand, cure, and prevent diseases. A social scientist, however, defines medical care as a system of social institutions in a larger social structure. Since medical care is given by specialized personnel, it presents to the social scientist several problems in the sociology of professions. Since much medical care is given in organized settings, it can also be

studied from the viewpoint of the sociology of formal organizations.

The demand for medical care

Medical institutions cannot originate without a market. Anthropological evidence suggests that recognition of physical and emotional problems by potential patients is universal among the world's populations: whether he is a Western city dweller or a peasant in an underdeveloped country, the human being is aware of discomfort and an inability to perform his normal social roles. However, the decision to take practical action and the choice of remedies vary widely according to the social system and according to the individual's statuses in each social system.

Religion and science. The meaning of illness and the practical action deemed appropriate in a society derive from the prevailing bodies of religious and scientific thought. In many underdeveloped countries, widespread beliefs attribute injuries and illness to alienation from divine forces or from social obligations. For remedies appropriate to the imputed causes, large numbers of people may rely on personal rituals or on the guidance of priests and folk practitioners. Where Western medical institutions have been imported into such societies by governments or missionaries, they may be used by only the small minority that is urban and Westernized (Williams & Scharff 1960, p. 18).

Extensive public use of medical care depends on widespread acceptance of certain doctrines about God and man: human life on earth should be preserved; the alleviation of physical discomfort does not contradict divine intent but may even serve God's will; practical action to save life is not inconsistent with divine purpose or church obligations. These doctrines have been prominent in Christianity, classical Islam, and Judaism. For these reasons, public utilization of therapeutic and preventive medicine has been widespread in the ancient Middle East and in the modern West. As Western religions spread in Asia, Africa, and Latin America, or as contrary traditional religions are redefined to tolerate or encourage the alleviation of discomfort by practical secular action, public utilization of scientific medical institutions increases.

In many societies, the prevailing religious and scientific beliefs define illnesses differently and, thus, teach a range of responses. For example, externally visible injuries and infections may be attributed to mundane events, while internal physical and mental malfunctions are believed to originate supernaturally. Since direct physical remedies are considered appropriate for the former and magical or propitiatory methods are alone believed effica-

cious for the latter, the population may bring its surgical and infectious problems to the Western-style doctor and hospital, while retaining clergymen and folk practitioners for internal and mental illnesses.

The referral of particular categories of people is often a function of religious belief. For example, folk religion in some Arab and Asian countries assumes that the evil eye and divine wrath fall particularly heavily upon babies and children. Therefore, pediatric illnesses may be thought irremediable; few children are brought for medical care; and pediatrics remains an undeveloped specialty in medicine (Cameron 1960; Williams & Scharff 1960, pp. 18, 32, 34).

Other social determinants. The demand for medical care varies with other broad characteristics of society, such as the general levels of urbanization, literacy, prosperity, and industrialization. Poverty breeds disease and neglect, and consequently the world's numerous underdeveloped countries have potentially huge numbers of patients (Brockington 1958, part 2). Illiteracy prevents many citizens from learning where to find medical care, and services are often inaccessible in the rural areas, where much of the population lives. However, as information spreads about the availability and efficacy of medical installations, public use increases. As urbanization rises, so does the number of patients; in the cities of underdeveloped countries, vast throngs of ill persons tax the outpatient clinics and inpatient wards of public hospitals (McGibony 1961, pp. 51–52; Mazen 1961, pp. 40, 72, 273–275).

Within each country, social class and literacy appear to correlate with the use of medical care. The lower and poorer social classes may have the greatest number of physical and mental problems. But the higher classes make greater use of medical services because of their greater understanding of medical services, their social sophistication, and their ability to pay (Kadushin 1964). The problem varies by social class: for example, in the developed countries, coronary disease and ulcers are found more often among the upper class, infections and tuberculosis more often among the lower class (Freeman et. al. 1963, chapter 14 *passim*; Susser & Watson 1962, chapter 3).

Family structure. The demand for medical care is affected in several ways by family structure. In the Muslim countries and in some others, religion and custom decree that women are to work and live solely within the family circle. Therefore, women hesitate to visit the hospital and particularly to become inpatients, since this would involve

immodest contact with male strangers. More men than women use medical services in the Muslim countries, but the opposite is true elsewhere, particularly in the West (compare Mazen 1961, pp. 213–214 and Fehler 1961, p. 397). Medical specialties involving female modesty, particularly obstetrics and gynecology, are developed far more in the West than in the countries with sheltered women.

In preindustrial societies, the breadwinner is indispensable to provide current income, and the mother cannot easily be spared from her family duties. Thus, young adults may postpone medical care, particularly if inpatient hospitalization is likely, and medical services are used predominantly by children, the elderly, and severely ill young adults. However, in some underdeveloped countries, babies and young children occupy such a subordinate position in the family that they are brought for medical care much less often than adults (Steuer 1961, p. 335). In general, the utilization of medical services is higher in the industrial countries, not only because family nursing is deemed less efficacious than expert hospital or clinic treatment, but also because employers expect efficient performance and because urban living conditions make home care difficult. The modernization of underdeveloped countries includes the establishment of Western-style medical institutions and the propagation of Western health norms, and consequently the foregoing cross-national differentials in the utilization of medical care will diminish.

Medical practice

Since every society has the functional problems of explaining illness to the sick and their families and of guiding practical action, each society develops a body of medical theory from its basic ideas about the universe, life, and man. These theories vary in their empirical utility and in their implications for remedial treatment. Some of the principal civilizations—notably, European, Islamic, Indian, and Chinese—derived considerable and still influential systems of medical theory from their religions and ontologies (Castiglioni 1927).

Each of the principal medical traditions became institutionalized in the form of a theoretical literature, recognized practitioners, and educational techniques for transmitting knowledge and remedial skill from one generation of practitioners to the next. Much of the training has been didactic, but some—particularly in the Greek-Islamic-Western tradition—has made the neophyte an apprentice or observer of a practitioner at work.

Western medicine. Transmitted to Europe by certain medieval Italian universities, Greek-Islamic

medicine ultimately proved the most productive in empirical knowledge and in therapeutic success. Several characteristics of European thought and society seem to have been crucial conditions for its growth. First, much of Western scientific thought has been inductive and empiricist, and some of this thinking contributed to medicine. Thus, although deductive and metaphysical theory was not absent from Western medicine, and although the speculative system builders vigorously fought new trends, simultaneously there developed a medical tradition of observation, experimentation, and critical verification of facts and therapies. Western medical knowledge and remedies—particularly in recent centuries—have been under continuous revision in the light of new evidence, to a degree found in no other medical tradition. Furthermore, the empiricist spirit of Western medicine has resulted in a tradition of medical education in hospital wards and experimental laboratories, to a degree found nowhere else (Shryock [1936] 1947, especially chapters 1–11).

Second, religions in much of the world insist on preserving the complete body of the deceased person, usually as a condition for his heavenly salvation. But Christianity distinguishes more clearly between soul and body, and it pictures the salvation of the soul while the body rots. Therefore, Christianity has been able to tolerate the widespread use of autopsies, while most other religions discourage them, and much of the physiological and therapeutic knowledge of Western medicine has resulted from post-mortem examinations. Potentially productive medical traditions in other societies, such as Islam, have been stunted because the dominant religions forbade autopsies.

A third reason for the greater success of the Western medical tradition has been the West's technical inventiveness. This approach industrialized the West's economy. But even before the industrial revolution, the West's gadget-consciousness introduced into its medical research and practice extremely fruitful diagnostic and therapeutic devices, such as the microscope and thermometer. During the nineteenth and twentieth centuries, the industrial revolution has enabled Western medicine to employ even more complex devices, such as the X ray or the anesthetic equipment essential for thoracic surgery, which could not be invented by the world's numerous preindustrial societies.

Finally, the West has had a long tradition of bureaucratic organization. In this respect, of course, the West has not been unique; but its distinctive achievement was to apply such methods to the financing, staffing, and dissemination of med-

ical care. Nationwide systems of public health regulation, hospitals, medical education, and health insurance evolved under the auspices of churches, governments, and voluntary associations. All the foregoing variables—cumulative scientific knowledge, technology, and extensive formal organization—have combined in recent centuries to produce a highly developed system of medical care in the West and, increasingly, through cultural diffusion, in other societies.

Doctor and patient

The individual doctor renders medical care to the individual patient in a variety of settings: the patient's home, the doctor's office, hospitals, or polyclinics. The relationship between doctor and patient in the West is thought of by social scientists as a special case in the sociology of professional-client relationships.

American sociologists' thinking about the doctor-patient confrontation has been greatly influenced by a theoretical model suggested by Talcott Parsons (Parsons 1958; Parsons & Fox 1952). The sick person, according to this model, is temporarily exempt from his normal social roles but is expected to perform certain well-defined patient roles. The doctor specializes in diagnosing and solving the patient's problems in accordance with the social norms of his profession, and he has the social responsibility of controlling the patient for the good of society and of the patient himself. The patient is expected to obey the doctor and strive for recovery in accordance with the expectations of each stage of his treatment. Gradually the dependence of patient upon doctor diminishes, and the patient resumes his normal family and economic roles.

Parsons' analysis pictures an intelligent and ambitious patient and presupposes the achievement-oriented social system of the West. Research needs to be done in order to determine its applicability in non-Western societies with different values and with large proletariats possessing less ambition and more pessimistic medical prognoses. [See PROFESSIONS.]

Occasionally social scientists have observed the relationships between doctor and patient in hospitals and private offices, and they have attempted to trace the clinical consequences of the social structures governing this two-person interaction. For example, the class differences between doctor and patient have been found to affect the success of their clinical relationship: since the less educated patient is less able to communicate with the doctor in the latter's own vocabulary, he is asked to give fewer reports, and he receives fewer explana-

tions and fewer instructions for home care than do patients of higher social classes (Freeman et al. 1963, chapter 11 *passim*). Another example of research on the social conditions governing relations between doctor and patient is Burling's finding that the patient's confidence in the doctor increases if the patient is not socially isolated but enjoys close personal relations with family members and with other patients (Burling et al. 1956, chapter 3).

Many of the clinical decisions of the doctor have been found to depend on his own social relations within the medical profession and within the larger, lay community. For example, the doctor's ethnicity, family origins, and prior educational career—as well as his professional skill—affect the types of colleague networks and hospitals that he will join, and these contacts will determine the quality of his facilities, the skill of his consultants, and the affluence of his practice (Hall 1946). Adoption of new drugs—and possibly other innovations—by the individual doctor occurs earlier and more often if the doctor is closely related to a network of colleagues, and the adoption pattern for the network is led by certain doctors with a proclivity for adopting new things generally (Coleman et al. 1959).

The hospital

In many societies, all patients are treated in their homes by family members, with occasional visits by the priest or medicine man or with occasional visits by the patient to the medicine man. Among a few preindustrial peoples—such as the early Hebrews and some contemporary African tribes—the medicine man maintains beds where he can watch and treat patients in proximity to his own medical supplies or religious shrines. However, only a few civilizations have produced hospitals in large number and as important centers of medical care.

Certain conditions in the social structure seem essential for the existence of an extensive and important hospital system. The society must have skill in creating and running organizations. The religious and other social beliefs must legitimize the diversion of substantial resources for the treatment and maintenance of sick strangers. Sick people and their families must accept the idea of living away from home under the control of strangers. Finally, the society must produce and train enough people qualified to work in hospitals and must motivate them to care for sick strangers.

Extensive hospital programs occurred in the past under the ancient Hebrews, in ancient India during a period of synthesis between Buddhism and Hinduism, and in medieval Islam. Religion was a

powerful motive in all three societies, since it taught that human life should be saved, that illness was a remediable blight upon life, and that scientific knowledge could properly be applied in combating disease. Resources were readily available for hospitals, and the Hebrew and Muslim religions preached that private charity for the poor and sick were necessary conditions for salvation. Islam and India were ruled by governments which recognized that large cities could not be run efficiently without therapeutic and custodial centers. Furthermore, both Islam and India, during the periods of their hospital programs, had experience in creating networks of formal organizations—in Islam as a result of ecclesiastic work and in both countries as a result of powerful and active governments.

However, the hospital programs soon declined in all three societies because the necessary social conditions were incomplete. Hospitals require dedicated staffs, and none of these religions preached the duty or desirability of lifetime careers of caring for sick strangers. In fact, the caste taboos of Brahmanical Hinduism discouraged a large number of employees from working in the same place and from giving all necessary care to the general public. None of these countries had monastic traditions, and thus, the church could not run hospitals when the state was conquered by foreigners—in the Hebrew and Muslim cases—or when the state lost interest in running hospitals—as in India and the unconquered parts of Islam.

The role of Christianity. Christianity has been far more conducive to the development of hospitals than other world religions. Like the others that encouraged limited hospital programs, Christianity preached the value of human life and the desirability of preserving it through applied science. But above all, Christianity provided the doctrinal and organizational basis for hospital staffs. Humble and charitable care of the sick and poor was commended as one of the principal paths to salvation. Instead of sheltering women and thus discouraging nursing careers—as did Islam—Christianity encouraged unmarried women to do charitable work among the public and even to live away from home if necessary. Not only did Christianity legitimize hospital employment by laywomen; the Catholic church organized brotherhoods of monks and orders of nuns who nursed hospital inpatients as their apostolic mission. Employing bureaucratic procedures learned in large part from the government of the Roman Empire, the church organized hospitals, financed them through its extensive fund-raising machinery, and maintained them. Thus, Christianity's ecclesiastic structure produced

a continuity in hospital affairs regardless of the fluctuations in state policy.

For many centuries, European hospitals were run by the church or by associations of laymen affiliated with the church, and they were staffed by nuns. For much of their history they were custodial institutions, where sick and dying people were maintained and given religious guidance. Greek-Islamic therapy was introduced when some of the medieval nursing monks attended southern Italian medical schools. Thereafter, hospital systems created and maintained by the church also became the workshops of doctors and centers of medical education. European hospitals became secularized as the function of religion changed in Western social structure, as medical science became more successful and influential, and as lay governments became more powerful and more responsive to their citizens' demands for social welfare. In the late Middle Ages the church forbade monks to practice surgery and restricted their other medical work; lay physicians were welcomed into the hospitals and soon commanded all their medical practices (Rosen 1963).

Secularization of hospitals. Between the Reformation and the present day, many church-affiliated hospitals have been taken over by governments, and many new hospitals have been created by governments or by secular owners. Even after these transfers to government, Catholic nuns and Protestant deaconesses continued to work in hospitals; however, a new occupation of trained lay nursing arose in the late nineteenth century, and these nurses have been taking over the numerous jobs that cannot be filled by the now contracting religious orders. Church-affiliated hospitals staffed by nuns can still be found in countries where the church must seek new converts and retain the loyalty of its own communicants, such as in non-Christian societies and in the Western countries with mixed religions (for example, Germany, Holland, Switzerland, and the United States).

As Western medical care spreads throughout the world, so does the Western hospital in its present secularized form. However, a serious obstacle is the recruitment of enough lay graduate nurses in non-Christian societies. Christian values seem to be an important recruitment motivation for lay nurses, just as they have been for nursing nuns.

It is evident from unpublished research by the present author that underdeveloped countries without large Christian minorities have great difficulty in staffing their hospitals.

The rise of scientific medicine. Since the hospital is organized to protect and treat sick people,

its goals, structure, and functions depend on the current state of medical science. As a result of the great medical advances of recent centuries, the Western hospital has been transformed. Previously, the hospital was a charitable establishment to care for the helpless and protect society from the infected. In order to perform such work, only a small staff of supervisors and unskilled attendants was needed; only a few doctors visited, to give quick treatments or to perform occasional clinical experiments. Since these were custodial institutions for the poor and since the wealthy could afford home visits by doctors, the higher classes were treated and housed in their homes. Because infection and pain were common in hospitals, much of the public avoided surgery and feared hospitalization.

Modern medicine learned to classify diseases and distinguish among the treatments for each; the hospital needed to separate patients according to disease for distinctive treatment by category, and therefore, modern hospitals became departmentalized. The understanding of sterile technique and the introduction of antiseptics reduced cross-infections, made surgery and obstetrics safe, and increased therapeutic success and public confidence. Surgery also became more successful and popular because of the introduction of anesthetics. Surgical facilities grew in hospitals, and surgeons gained prestige and wealth. The wards became places for continuing treatment and were recognized as places of potential but preventable cross-infections. Scientific nursing education was introduced, closer controls were instituted over lower nursing ranks, and nursing staffs were greatly increased in size. The introduction of laboratories, operating theaters, and many ancillary services increased the size of paramedical staffs and raised the cost of hospitals. Since medical specialists needed to treat their patients by means of these facilities, members of higher social classes were hospitalized. The physical appearance of existing hospitals was improved, and private hospitals originated. Since specialty training required acquaintance with the advanced techniques found in hospitals, large and disciplined medical staffs were created, and many hospitals added educational and research goals to their mission of patient care. To administer such large and complex organizations, there developed new occupations specializing in hospital management; to supply the hospitals there arose new and immensely profitable pharmaceutical and equipment industries.

Hospital organization. Within individual countries—and particularly in the United States—social scientists have studied interpersonal processes within hospitals, using the same concepts that they ap-

ply to any other organizations. For example, American sociologists have long been interested in latent social processes and in the entire set of functions and dysfunctions resulting from certain institutional arrangements. Thus, American medical sociologists have not only studied the manifest hospital structure and its successes but have pointed out the presence of latent processes with paradoxical outcomes. The hospital, they say, is manifestly dedicated to the provision of means for treating patients successfully. However, every organization requires an administrative structure to arrange its resources economically and to control deviant behavior. Thus, therapeutic and administrative structures exist simultaneously in the hospital, each with its own priorities and personnel. Emphasizing one set of goals (such as administrative order) is dysfunctional for maximization of the other structure's goals (such as patient care), and conflicts occur between the two lines of authority (such as the lay administrators and the doctors). Several studies of mental hospitals note the dilemma of combining organizational imperatives and therapy: the custodial structure necessary to control patients and maintain order is dysfunctional for mental care. [See ORGANIZATIONS, *article on ORGANIZATIONAL GOALS*; see also Freeman et al. 1963, chapter 10, and Reader 1959.]

A specialist in administrative medicine might primarily study the formal organization of hospitals, but sociologists—whether observing factories, schools, or hospitals—search for the informal social structures that may substantially deviate from the formal chain of command and that may powerfully influence the system in action. Some American medical sociologists have been participant-observers in hospital wards. They have described the informal social system among patients, and they have identified how this informal ward society alternately raises and lowers the morale of individual patients and alternately supports and disturbs each patient's relationships with the hospital staff (e.g., Fox 1959). From such research in mental hospitals has come the advice that the individual patient's recovery depends not only on treatment received during the hours reserved for formal therapy but also on harmonious relationships involving all patients and staff members throughout the day. The successful "therapeutic communities" are said to have democratic decision making, full communication of ideas and grievances, stable and rewarding careers among staff members, a proper balance between freedom and control, and an ideal combination of self-reliance and group support (Stanton 1954).

Quality of medical care

From the viewpoint of the social sciences, medical care is a strategic area for studying the institutionalization of social values and of applied scientific technique. However, from the viewpoint of the public and of an increasing number of medical practitioners, the proper task of the social sciences is to evaluate and improve the quality of care. Therefore, many medical organizations have retained social scientists to gather information and give advice. Some of the resultant studies deal with the training of doctors and nurses: the formal and informal organization of the curriculum, of the student community, and of the hospital are found to promote student learning in some ways and to inhibit it in others; and this information has been used by curriculum planners and administrators in the improvement of their instruction.

Determinants of good care. Several studies have attempted to locate elements in the social organization of medical care that affect the quality of treatment. Usually this research involves collaboration by physicians and social scientists: the former identify the actions constituting "good medical care," while the social scientists contribute knowledge about research techniques and ideas about the possible determinants of good care. For example, O. L. Peterson and his associates (1956) observed the work of general practitioners and concluded that class standing in medical school, length of preparatory education, exposure to refresher courses, and other experiences are strongly related to several indicators of good care. Contrary to common beliefs, involvement in medical society affairs, prestigious hospital appointments, hours of work, and certain other variables were found to have little relationship to good care in this sample.

In an ambitious study of ten hospitals, Basil S. Georgopoulos and Floyd C. Mann (1962, chapters 5 and 8) discovered that certain social attributes of the hospital correlated more strongly with quality of care than did other commonly credited determinants, such as the volume of material facilities, size of budget, number of beds, and ratio of personnel to beds. The organizational characteristics associated with good care were: high coordination throughout the hospitals, harmonious relations among departments and between doctors and nurses, lower absenteeism among graduate nurses, and efficient but congenial management. In another organizational study of hospitals, Melvin Seeman and John W. Evans (1961) found that the informal social organization of the ward affects the clinical performance of interns and nurses: where

power inequalities and other forms of social distance are greater, efficiency and skill are lower.

Some social research methods have been used to gather expert opinions about the nature and sources of good care. For example, Milton C. Maloney and his associates (1960) used survey techniques to get a sample of expert opinion about the quality of care: they asked doctors about the care the doctors obtained for themselves and for their families. These expert judges preferred treatment by full-time specialists in metropolitan medical centers.

Doubtless applied social research will become an increasingly recognized fact of medical care in all countries. Modern medicine is devoting more attention to the "stress diseases" and other medical conditions that seem related to social roles. The organizational problems of medical care are rising because of increased costs, scarcities of personnel and of services, and because of the demands by social planners for greater efficiency and economy in medical administration. Teamwork among clinicians, administrators, and social scientists may consequently become commonly accepted as the means to a common goal of better quality care.

BIBLIOGRAPHY

Interest in social determinants of medical care first entered the literature of the field through the writings of several leading medical historians (e.g., Sigerist 1960; Shryock 1936) and through research in epidemiology and public health (see the bibliographies for the articles on these two topics).

Sociologists, social psychologists, and other social scientists began to write about medical care only in recent decades. Much of their work has been designed to provide practical information for psychiatric hospitals, the curriculum committees of medical and nursing schools, epidemiologists, and other medical practitioners with practical problems requiring knowledge of the facts. However, some research has been designed by social scientists to test hypotheses derived from their own disciplines. The voluminous American literature is summarized in Freeman et al. 1963, and some of the principal studies are reprinted in Jaco 1958. Research by social scientists is also well advanced in Great Britain, where a group of specialists in "social administration" provide facts and advice about all aspects of social policy, including health (Susser & Watson 1962). Similar work is beginning elsewhere: for example, König & Tönniesmann 1958 summarizes the research in Germany. Bibliographies of the American and European literature are provided by Freidson 1961, 1962 and Pearsall 1963. Much of the social research on the quality of care is summarized by Anderson & Altman 1962.

Several writers on public health and administrative medicine have summarized the health problems and forms of medical organization in the world (e.g., Brockington 1958). As yet, no social scientist has written a general survey of

the variations in the social organization of medical care throughout the world.

As social scientists have written more about medical care, their ideas have become more widely accepted in the writings of clinicians, and particularly by psychiatrists. An increasing number of writings by physicians, nurses, and medical administrators about the proper management of medical organizations and about the proper treatment of patients incorporate concepts and generalizations about the effects of the patient's family settings, the community's culture, the social relationships between patient and clinician, the personality traits of persons experiencing stress and social isolation, and so on (e.g., Balint 1957).

III ECONOMIC ASPECTS

The economic aspects of medical care encompass a broad and diverse area. It can include discussion of medical care utilization by various income groups, licensing arrangements, incomes of practitioners, fee structures, and so forth. This discussion will be limited to three topics: (1) some of the special characteristics that distinguish medical care from other goods and services; (2) the various alternative mechanisms for financing medical care services utilized at the present time;

(3) general economic problems related to alternative patterns of financing.

Special characteristics

Medical care, although generally viewed as a consumption commodity, has come to have a special status among the wide variety of such goods and services. This status affects its organization, the amount of resources it commands, and the patterns used in its financing.

Social-psychological factors. The view that medical care is somehow "different" is mainly an outgrowth of what may be called social-psychological factors. Medical care is felt to be (and obviously often is) intimately related to health and to life itself. The public associates medical care with dramatic lifesaving procedures, with the treatment of potentially fatal illness, and with the alleviation of suffering and pain. Since life is not considered a luxury commodity, those things which are believed to be associated with its preservation, e.g., medical care, have come to be considered a "human right." As a consequence, it is felt that the amount of medical care received—that the right to life or the prevention of pain—should not depend on the individual's income and purchasing power. Actual practice, of course, is often at wide variance with beliefs and declarations in this area.

Unpredictability of need. A number of significant economic distinctions between medical care and most other goods also impel the public to the view that the financing and organization of medical care should be treated differently from the financing of other goods and services. Perhaps of primary importance is the fact that illness, and consequently the need for care, is unpredictable for the individual, although it is predictable for the group. The individual, therefore, finds it impossible to anticipate the frequency of medical care, the amount he will need, and the costs that will be associated with such care. Furthermore, the economic burden imposed may be extreme—the illness may be severe and the economic consequences catastrophic. Not knowing the costs, he cannot save the appropriate amount in advance of an illness of unknown severity that may occur at some unknown time and with unknown frequency. This matter assumes increased significance, since real limitations exist on the possibility of postponing medical care purchases.

Although postpayment over a period of time would be a possible remedy for part of the problem, difficulties with that device are many: (1) illness may affect both short-run and long-run earning power and thus make such postpayment difficult, perhaps impossible; (2) the service rendered can-

not be repossessed if there is a failure to meet payments; (3) the individual may feel that he has little or nothing to show for the medical care received, i.e., he is no better off than before he became ill and is simply back to the pre-illness state, to which he feels he might have returned even without the care; (4) treatment may involve discomfort and pain, neither of which is certain to make one feel well disposed to those who rendered the treatment and thus to meeting periodic payments to the provider of care; (5) the individual does not consider that he is continuing to derive benefits from the service rendered in the past—as contrasted with the continuing pleasures derived from the purchase of consumer durables and other goods.

Externalities. A second characteristic of medical care services not shared by most other commodities involves externalities. These are present when benefits (or costs) accrue to others because the individual takes a particular action. The purchase of some types of medical services clearly involves such externalities. This is most evident in the case of communicable disease. All of us derive benefits from the immunization of others and from the prevention and treatment of the communicable diseases that affect them. The benefits to society, therefore, exceed the individual consumer's benefits. Conversely, there are costs to individuals when disease is not controlled in some other part of the population. The matter of externalities can be viewed even more broadly if we include satisfaction as well as dollar benefits in our consideration. If others are crippled, sick, or disabled, and if we are made uncomfortable by knowing about or seeing these conditions, then the benefits to society of rehabilitation or cure exceed the benefits accruing to the individual who is rehabilitated or cured. The increase in social satisfaction should, therefore, also be included in the calculus.

Economic theory has shown that where positive externalities (external benefits) exist, the individual underinvests in the commodity, from society's standpoint. Thus the private sector underinvests, insofar as there is insufficient philanthropy or absence of compulsion. This characteristic becomes one of the bases for public intervention in the health sector and is one of the reasons that government is often the major financing agent for certain types of health expenditures. [See EXTERNAL ECONOMIES AND DISECONOMIES; WELFARE ECONOMICS.]

Investment. Yet another special feature of medical care is implied by the use, in the preceding paragraph, of the term "invest." Medical care is in part a consumption commodity, but also in part

an investment good. The purchase of medical care today increases the level of health and thus raises productivity in the future. Such sacrifice of current consumption in order to raise future output is the essence of all investments. Thus, the term "investment" need not be applied solely to expenditures on material capital. Accordingly, the analysis of public policy toward medical care can be cast in an investment framework.

Quality assessment problems. An additional significant distinction between medical care and other services is the consumer's relative inability to judge the quality of the product he is purchasing. This matter has even greater importance when it is recognized that sins of omission or commission on the part of the physician or persons working under his direction may have serious and non-reversible consequences. Even *ex post* evaluation of quality by the consumer is difficult, and the satisfaction or dissatisfaction with the medical care provided may, therefore, be based on various extraneous factors. Since medical care may involve more serious matters than are involved in the purchase of other consumer goods, and since the search to find quality care is more difficult than with other goods, some measure of protection is afforded the consumer by licensing arrangements. In this manner authorities "guarantee" some presumed minimum level of competence. The economic issues in such licensing arrangements are many, since, depending on the standards set and the responsibility of those who provide licenses, supply may be artificially and unnecessarily restricted, with consequent increase in prices for services and in incomes of practitioners not sufficiently compensated for by increase in quality of care. [See LICENSING, OCCUPATIONAL.]

Alternative financing mechanisms

The special characteristics of medical care have played a role in inducing governments to participate actively in the medical care sector. The form that such participation has taken has differed greatly and is a product of institutional and ideological constraints. Nevertheless, the role of government in the health sector and in financing health care is acknowledged in all countries. This role often takes the form of government participation in funding or distributing medical care for specific categories in the population. These categories of persons may be defined by specified health characteristics (e.g., the blind, the disabled), by age characteristics (e.g., the aged, children), by economic status (e.g., the indigent, the medically indigent), or by other special characteristics that define

a particular population group (e.g., veterans, migrant workers). On occasion, combinations of these characteristics are utilized to determine eligibility, and individuals must then meet more than one criterion. Government participation and support, of course, need not be confined to categories of persons and in some countries covers the total resident population.

Voluntary insurance (United States). Voluntary health insurance has developed as one method of financing designed to meet the problem of unpredictability of illness and the need for medical care. The insurance principle lends itself to application in the health area, although it is relatively difficult to apply to certain health expenses and to certain population groups. This type of financing is most highly developed in the United States, where hospital insurance and surgical-medical insurance are provided both by nonprofit plans and by commercial insurance companies.

The expansion of private voluntary health insurance in the United States began in the 1930s with the development of Blue Cross plans for hospital coverage (with backing by the American Hospital Association) and Blue Shield plans for surgical-medical insurance (with backing by the organized medical profession). These plans are nonprofit and serve local areas (usually entire states), although national coordination is provided.

Commercial insurance companies entered the field in the late 1930s, largely through group coverage and utilizing arrangements for reimbursement of charges up to specified amounts rather than for provision of specified services (as in the nonprofit hospitalization plans). Commercial carriers competed successfully with the Blue Cross and Blue Shield plans. In part this was because the "Blues" used community rating: the rates charged for each of the various contracts offered were the same for all groups in a community. Commercial carriers used experience rating, wherein the rates charged any single group varied with the experience of that group. As a consequence, low-risk groups and individuals often found it advantageous to deal with a commercial carrier where premiums reflected their own experience and utilization of services rather than the average experience, including that of the high risks, in a community. The greater the number of low risks who left the "Blues," the higher the insurance rates rose for those remaining. Thus those who previously found themselves on "the margin" now found it advantageous to shift to commercial carriers. This mechanism could, in theory, continue indefinitely. It is one of the important considerations in the social insurance area and is often used to argue

for a compulsory element in social insurance. As a result of the force of this process, experience rating is now widely used even by those plans which originally rejected it on philosophic grounds. With experience rating, high-risk groups (e.g., the aged) find that the rates charged are higher than would be the case under community rating and that it becomes more difficult to participate in the plan.

This problem, as well as a number of other conditions, led the United States to institute, effective in 1966, a public system of health insurance, as part of its social insurance system, providing for limited financing of some medical care for persons 65 years of age and older. The pressure for such a system of insurance was also heightened by the fact that the aged often are not members of groups eligible for group insurance coverage. Insurance rates for individuals are significantly higher than group rates (and not only because the employer frequently pays a portion of the premium under group coverage). The high medical expenses of the aged and their relatively low financial resources compound the problems of finance. [See AGING, article on ECONOMIC ASPECTS.]

It is estimated that in 1965 about 80 per cent of the civilian population in the United States had some insurance protection against the costs of basic hospital care, about 75 per cent had some surgical expense protection, and almost 60 per cent were eligible for some additional coverage for in-hospital physician visits. Although the benefits met about 70 per cent of the total cost of hospital care, only about one-third of total consumer expenditures for personal health care were met by insurance. In the United States, health expenditures are financed largely by the private sector: of the \$37,000 million of national health expenditures in 1964 (5.8 per cent of the gross national product), 74 per cent came from the private sector and only 26 per cent from the government—equally divided between the federal government on the one hand and state and local governments on the other. About 50 per cent of all personal health service expenditures were paid for by the recipient of the services (or his family), while third parties (government, insurers, etc.) paid for the remainder.

The problem of high-risk groups under experience rating in a voluntary insurance plan can be solved by a compulsory insurance program or direct government provision or financing of services. However, the traditional arguments that are used by those who favor approaches involving more government participation go beyond the solution of the difficulties that some groups and individuals face under experience rating. They include matters such as ease and economic efficiency of administration.

comprehensiveness of care, coverage of the total population (including those groups that voluntary insurance finds it difficult or inefficient to reach or whose economic status is so low as to inhibit purchase of insurance), more ready control of inflation in medical care costs, increased equity in financing of care, and more possibility of increasing emphasis on certain aspects of medical services, e.g., preventive care. The success with which any of these objectives would be met would depend upon the particular characteristics of the health insurance or financing plan. The social security characteristic of a plan does not in itself guarantee comprehensiveness of coverage, quality of service, control of inflation in medical care prices, equity in financing, and so forth. Just as the voluntary private health insurance system can take many different forms and thus meet different problems, raise different issues, and resolve basic questions in different ways and with varying degrees of success, so too can each alternative basic system for financing or providing care.

National Health Service (United Kingdom).

One type of approach to the financing and provision of medical care services is that employed in the United Kingdom under the National Health Service. Medical care services (rather than reimbursements) are provided all residents. The major costs of the program are financed out of general revenues, although small weekly contributions are paid by workers and employers. Some cost sharing by the patient for medicines and selected other items is also provided for. All residents are eligible for such services as general and specialized care, dental care, and hospitalization. The services are provided by doctors and druggists who are under contract to the National Health Service and by public hospitals owned by the central government. The physician receives a payment for each person on his rolls. This capitation method of payment of physicians encourages patients to have a continuing relationship with a particular general practitioner. The capitation method of payment, as contrasted with a payment for services rendered, is considered not only to be a good financial arrangement but also to represent a basic philosophical approach to medicine which is believed to have advantages that go beyond ease of administration.

The United Kingdom thus has a pattern of financing and organizing medical care substantially different from that of the United States, or from that which the latter will employ for those 65 years of age and over. Perhaps 85 per cent of all health expenditures in the United Kingdom are paid for by third parties, a much larger percentage than in the United States. The amount of resources allocated

to health services in the United Kingdom (4.2 per cent of a lower GNP) also differs from that in the United States (as indicated previously, 5.8 per cent of GNP). It is not clear, however, what part of these, and other, intercountry differences is attributable to differences in relative price levels (i.e., the relative costs of health services as compared with other goods and services in each country), differences in efficiency in the health sector, differences in levels of health and "needs," differences in quality of care, and differences in real resources devoted to health care. But it is clear that there do exist wide differences in the percentage of GNP devoted to health services in various countries. The significance and implications of these differences have yet to be thoroughly examined, but they do not seem to be related to the prevailing patterns or sources of finance or to the significance of the government sector in the health area.

Basic alternatives. The three main patterns of nonmarket provision of medical benefits in the various countries are (1) provision of direct services through facilities owned and operated by the government or by a social insurance fund; (2) services provided to patients, with the provider of services being paid directly by the government or fund; (3) reimbursement of fees paid directly by patients to providers of the services. As will be discussed below, the need for rationing of services still remains under the various arrangements, and patients are, therefore, often called upon to share the costs of the services rendered.

While a number of countries provide comprehensive medical services to all residents (although patients may pay part of the cost of the service provided), and an additional number of countries provide various selected therapeutic services, the particular benefits available and the mechanisms by which care is financed, provided, and organized differ greatly. In some countries medical services are provided to parts of the population under social insurance arrangements; in others, benefits are provided through membership in sickness funds to which employees, government, and (in some countries) employers contribute and in which membership is compulsory for certain categories of persons. Particular financing mechanisms are not necessarily tied to particular organizational arrangements, and thus many different combinations exist.

Economic problems

Need for rationing. Whatever the organizational pattern for distributing and financing medical care, the absence of a perfectly operating market for medical care presents certain difficulties. Although medical care is often viewed as a

basic human right, few scientific standards exist to define the amount of care that an individual "needs" or should utilize (i.e., the health benefits associated with given amounts of care). However great the public dissatisfaction with the medical care received, it is a fact that some individuals tend to utilize more services than they require or are believed to require. Furthermore, changes in the price of medical care services do tend to change levels of utilization. Declines in price are associated with increases in usage. Although an increase in utilization is often one of the purposes of government in creating systems that reduce price or provide insured health benefits, allocation problems remain. If society were to allocate sufficient resources to medical care so that no choice need be made between care for the individual who is dying but can be saved and the hypochondriac who wants reassurance (that is, if we were prepared to meet all increases in, and levels of, utilization), then rationing of medical resources would not be required. But such a situation is neither conceivable nor, given competing demands on resources, desirable. Thus rationing becomes imperative, and since society is willing to make some interpersonal utility comparisons regarding who needs care, the rationing scheme must incorporate the public's judgments.

Nevertheless, since there is little scientific agreement on desirable utilization rates (or on the relationship between utilization rates and levels of health), it is difficult to agree upon, set, and control such rates and to develop medically "optimal" rationing devices. In the absence of control of usage, budgetary, physical, and personnel shortages often appear, particularly because consumers often demand more care than the authorities have estimated would be the case. Attempts to balance resource limitations (including budgetary considerations) against the private decisions to visit physicians, to enter hospitals, and to utilize medical care in quantities determined by the individual (the balancing of "scarcity" and "human right") have always been necessary and have seldom been easy to achieve.

Were the health sector treated as most other services are generally treated, this particular problem would not exist. If consumers, out of their own budgets and without public or private subsidization, chose to "overutilize" services (judged by some scientific standard), this would be fully acceptable. The price mechanism would serve as a rationing device and, however "foolish" some might feel these expenditures to be, the consumer would be sovereign.

Since government plays a role in the health

field, even if in many cases it is limited to support for construction of physical resources (e.g., hospitals), or to training of personnel (e.g., supporting education), or to financing of certain types of care (e.g., for needy or aged persons), the government must be involved in the development of rationing devices to replace market forces. The same need exists, of course, when private physicians offer charity care.

Controlling utilization. The problem of "overutilization" (which can be viewed as the problem of scarcity) arises in all medical care financing mechanisms. The mechanisms of control when there is governmental involvement or control by a voluntary insurance carrier may, of course, differ. It is true that for many services waiting time, inconvenience, and even loss of income serve as deterrents to use. Even so, the use of "free" (but not costless) services may exceed the necessary, or "need," level. Therefore, additional monetary deterrents are often used, in the attempt to control overutilization. In particular, they are used to influence the consumer's choice between different types of care, e.g., office calls rather than house calls, home care rather than hospital care. Payment of some percentage of the costs (e.g., of hospital care) or in the form of some fixed charge (e.g., for a house call) is often instituted in order to induce the consumer to ration the care he seeks and in order to lead him toward those types of care which utilize less of society's economic resources. Such charges are also often made for prescription drugs. Since the use of such drugs is governed largely by the physician rather than by the patient, these charges may be instituted primarily as a device to cut the costs financed by the program rather than in order to change consumer behavior (although they do this as well).

The difficulty, sometimes unrecognized, with these procedures is that the money deterrent has a differential impact on individuals, depending greatly upon their "taste" and need for medical care, the accessibility of medical care, their total income, and the prices of other goods and services. What may be a small deterrent for some (perhaps the "optimal" deterrent from the point of view of the third party that finances the service or from the point of view of society) may represent a great deterrent for others and a trivial deterrent for still others. Income and price considerations thus re-enter the medical market place, although with less impact than would be the case in the absence of third-party payments. Furthermore, it is clear that the conflict recurs between encouragement to use services in the "correct" quantities and rationing of

care. No single level of fixed charges applying to all members of the population and designed to deter unnecessary use, but not to inhibit necessary use, can be the correct level for each individual. The operational consequences of the fixed charge will vary with a number of institutional considerations. It cannot be presumed that the consequences are necessarily severe (if maintaining accessibility is the primary goal) or are necessarily minor (if cutting utilization is the primary goal). The fixed charge in third-party payments does illustrate the fact that it is difficult to define that part of medical care which society considers a luxury and that part which is considered a need. With scarce resources a trade-off between goals is required—and difficult to determine.

Future developments in the provision and financing of medical care will be related to developments in medicine itself and to the acquisition of additional knowledge concerning the relationship between medical care and health and between health and productivity. The growing ability of medicine to prevent illness and to care for and rehabilitate the sick will bring increased pressures on the health sector. In most nations the role of government in health is likely to increase. In part this will take the form of intervention in the financing of services via social insurance or other arrangements. The financial responsibility, as well as the special characteristics, of medical care outlined earlier will result in government's assuming an increasing responsibility in the determination of the total amount of manpower and resources devoted to health and medical care and to the allocation of resources within the health sector itself.

The meeting of this responsibility will involve an increased reliance on new evaluative techniques. In recent years, partly as a result of the pressures for health expenditures and for planning of medical care in the less developed countries, and partly as a result of the refinement of benefit-cost analysis, the analysis of medical care has acquired an increasingly analytic economic content. In this approach, health and medical care are viewed in an economic context, and medical care programs are evaluated in relation to their cost and their potential impact on productivity through lower levels of morbidity and mortality. The economic value of man as a producer lies at the heart of the analysis, and the costs of various diseases are calculated in terms of the direct costs of treatment and medical care and the indirect costs to the economy of loss of productive power.

Decisions concerning the allocation of resources

to the health sector will, of course, not be based solely on the measurement of pecuniary costs and benefits. Nevertheless, such measurements are of assistance. It can, therefore, be anticipated that as understanding of the methodology of benefit-cost analysis grows, it will be increasingly used in governmental evaluation, planning, and budgeting processes.

II. PARAMEDICAL PERSONNEL

Eliot Freidson

I

PHYSICIANS

The physician is the most prominent among members of the generally recognized professions. He is seen by the public as possessing a higher standard than any other professional, and by the sociologist as the virtual prototype of his kind. While it would be a great mistake to confound what is peculiar to medicine with what is characteristic of professions in general, the study of physicians does offer the sociologist the opportunity to test both the truth and the utility of various orientations toward the concept of a profession.

One orientation sees a profession as an aggregate of people finding identity in sharing values and skills absorbed during the course of intensive training through which they all have passed in order to become professionals. In this view the professional is primarily a particular kind of person; one determines whether or not an individual "is" a professional by determining whether or not he has internalized certain given professional values. One explains a "bad" professional by reference to his inferior education, his defective character, or

similar variables. In short, one explains the behavior of members of a profession by reference to individual attributes and experiences bearing on conformity to a given set of norms.

Another orientation sees the profession as a group of workers joined together on the most general level by virtue of sharing a particular position in society and by common participation in a given division of labor. More specifically, the behavior of the profession is interpreted by reference to the way in which its work life is organized and the pressures toward conformity or deviance implicit in that organization. Here, the general assumption is that one defines a professional by his status, irrespective of the norms to which he subscribes, and explains his behavior by reference to the work structure in which he participates.

One difficulty in assessing the virtues of each of these orientations is the fact that there has been little attempt at testing them by sustained and detailed analysis of any single profession. And there has been little of the comprehensive comparative analysis that must be the ultimate goal of the sociology of medicine. Furthermore, because one of the marked characteristics of established professions is their relative freedom from lay intervention, from the conventional discipline exercised by industrial employers, and from the detailed directives of crafts unions, both organization and structure have been difficult to perceive. Professional organization is usually taken to be synonymous with the formal professional association, and the actual organization of work or practice has gone largely unnoticed.

This article, by attempting a detailed analysis of the medical profession and by focusing particularly on the way the performance of medical work is controlled, will try to clarify both the sociological characteristics of the medical profession and some of the issues germane to the sociology of the professions. (For a more extended analysis, see Freidson 1966.) Because of the paucity of systematic empirical studies from other countries, it is regrettably necessary to run the risk of parochialism and concentrate on medicine in the United States.

Medicine and the state

The foundation on which the analysis of a profession must be based is its relationship to the ultimate source of power and authority in modern society—the state. In the case of medicine, much, though by no means all, of the profession's strength is based on legally supported monopoly over practice. This monopoly operates through a system of licensing that bears on the privilege to hospitalize

patients and the right to prescribe drugs and order laboratory procedures that are otherwise virtually inaccessible to the layman. It is the state that grants this monopoly, the exact form of which varies widely throughout the world.

In the United States the profession, through its private associations, has very largely been given the right to determine how political and legal power bearing on medicine shall be exercised (see especially Hyde et al. 1954). In such countries as Great Britain, where the state has set up a national health system, representatives of the independent and private professional associations sit on both policy-making and administrative boards and negotiate with the state on various issues influencing practice (Stevens 1966). In the national health system of the Soviet Union there is no really private or independent representation of the profession that can negotiate with the state, although advisory and administrative councils do include physicians (Field 1967).

Clearly, the economic and political autonomy of the medical profession varies from country to country. What seems invariant, however, is its technological or scientific autonomy, for everywhere the profession appears to be left fairly free to develop its special area of knowledge and to determine what are "scientifically acceptable" practices. In national state health systems, although laymen do serve in policy-making and administrative positions, physicians tend to be administrative heads of practicing units and to be responsible for the determination of technical standards of equipment, procedures, and performance. Thus, while the profession may not be everywhere free to control the terms of its work, it is free to control the content of its work. Similarly, it is free to control the technical instruction of its recruits.

Medical training

The medical profession, quite as much as most sociologists, considers medical education to be the major single factor determining the performance of the practicing professional. By the content of his education the student is "socialized" to become a physician. The assumption is that in the course of such an education a new kind of person is created. Medical education in the United States is perhaps unparalleled by any other conventional professional training in its duration, its detail, and its rigidity. Medical school lasts four years after undergraduate college, followed by a fifth year of supervised practice in an accredited teaching hospital (the internship), and even more years for those seeking certification as specialists. It would seem

reasonable to think that such intensive exposure in fact molds the student into a particular kind of person. The Columbia University study of medical education (Merton et al. 1957) sought to demonstrate that the student, in the course of his training, develops a conception of himself as a doctor, absorbs the knowledge he needs in order to be secure enough to deal with patients without too much anxiety, and attains the capacity to cope with basic uncertainty in clinical practice.

Nonetheless, the students' perspective on their educational experience differs from that of their instructors. Indeed, one may expect there to be some kind of conflict between students and faculty by the very nature of their different roles. It is the unique contribution of the University of Kansas study (Becker et al. 1961) that it demonstrated the clash of perspectives in medical school and showed that the differences in orientation leading to "restriction of production" are not limited to industrial organizations. The consequences of this for the educational process were followed up in some detail. But the study also emphasized that the existence of this clash of orientations did not mean that there was nothing in common between the performance of students and the demands of faculty. It was discovered that two dominant values, held by the faculty, were adopted by the students and used by them to guide their learning experience and select their careers. These were the values of *medical responsibility* and of *clinical experience* (*ibid.*, chapters 12 and 13).

The value of medical responsibility refers to the traditional ideals of medicine, according to which the physician holds the life of a patient in his hands. It is the personal responsibility held by the physician working directly with a patient that requires him to take the blame for bad results. In the Kansas study, it was found that this value was impressed on the student by frequent faculty lectures about the way in which mistakes of omission or commission endanger the patient's life. Furthermore, faculty members frequently asked students how they would handle an emergency so as to avoid serious consequences to the patient. The value also featured in the organization of the training hospital, where the hierarchy of medical staff was ordered by differential access to medical responsibility, so that the unlicensed student was restricted to routine work having little relationship to life-or-death issues and the highest-status person was free to carry out the most complicated and dangerous procedures.

Clinical experience refers to first-hand contact with patients and disease. Such contact is the

ultimate justification for deciding to use one procedure for a treatment rather than another, and the experience so gained is valued because it provides a basis for therapeutic choice that is believed to be superior not only to the abstract considerations posed in textbooks but even to general, scientifically verified knowledge. It was observed in the course of the Kansas study that argument from experience was unanswerable except by the same type of argument from someone with greater experience.

These two values, Becker and his colleagues argued, order the choices the student makes from the range of experience offered by the medical school. These choices limit and direct his efforts in ways not anticipated or approved by the faculty. One of the student's most difficult problems is to select from the enormous mass of facts presented to him the information he is really to learn, for he cannot learn all of it. The idea of clinical experience, it was suggested, guides his selection of facts and information, leading him to discount basic science and focus on classes in which instructors give practical information not found in books—information that adds to his store of vicarious experience. By the same token, he struggles for personal clinical experience in his training, seeking opportunities for expanding it and deprecating routines he has already mastered. Similarly, he seeks tasks in which medical responsibility is apparent—reflecting some risk or danger—and avoids those in which it is not. And, finally, he responds positively to some patients as cases presenting him with valued responsibility and experience, and to others negatively as cases that take up a great deal of time without any valuable recompense (Becker et al. 1961, chapters 14 and 16).

The evidence seemed to show that choice of career also hinges on how far specialties provide the opportunity for medical responsibility and clinical experience. Thus, a desirable specialty is one which offers a wide variety of experience and in which responsibility is symbolized by the possibility of killing or disabling patients in the course of making a mistake. Internal medicine, general surgery, and pediatrics are therefore the most popular specialties, although the potentially "mechanical" character of surgery and the necessity of liking to work with children in pediatrics qualify their desirability for some students. At the other extreme, specialties like dermatology and allergy are unpopular because they are thought to involve little danger (and therefore little responsibility) or little variety (*ibid.*, chapter 20). National surveys of medical students in the United States have accumu-

lated a fair amount of data on specialty choice, most of which are compatible with this interpretation of the values underlying the choices of the majority of students. In the case of those choosing the less popular specialties—the best-investigated of which is public health (Coker et al. 1966)—specification of more detailed patterns of values is of course necessary.

Empirical types of practice

Unmentioned in the course of the discussion of medical training is one element of great relevance to performance: the technical knowledge and skill learned by the student. Here, it is necessary to say only that the student does in fact gain command over a great deal of knowledge and skill; what we must dwell on is the fact that this knowledge and skill is not necessarily retained or used after graduation from medical school. While in a modern industrial country like the United States all physicians share the same basic technical education, they do not all practice in the same way. In the few systematic studies of medical practice that have been made, the association found between medical education and subsequent performance was at best very weak. While the available evidence is scanty and poor, it points to variation in the organization of practice—that is, in the organized setting in which the professional works—as a more important influence than medical education or variation in performance. (For a summary of this material, see Freidson 1963; for the parallel case of the lawyer, see Carlin 1966.) Indeed, the analysis of work organization or practice is a critical problem for the sociology of the professions.

The central issue in the analysis of work is how performance is controlled. This issue constitutes a special problem for the analysis of professional work because professions, unlike other occupations, have successfully gained freedom from control by outsiders. Indeed, a profession is said to control its own performance. This is a rather unusual arrangement, worth understanding both in itself, as one type of control, and in its bearing on how, in our complex world, freedom and autonomy can be joined with responsibility. Let us examine the various organized practices in which medical work takes place to see how control over performance can be exercised. (For a more extensive examination, see Freidson 1963.)

One type of practice that is frequently held up as the ideal by professionals is one in which the individual is an entrepreneur, free to do what his own conscience and knowledge dictate. This is so-

called solo practice. While pure forms of solo practice are quite rare—invoking it as a norm reflects the individualistic ideology of the profession more than it reflects reality—we might ask what conditions must be met to assure that individuals practicing entirely on their own conform to professional standards. Assurance of adequate performance on the part of solo practitioners seems to require exceedingly careful recruitment policies and extraordinarily effective educational procedures. In essence, the practitioner must be able to resist all temptations to ethical or technical lapses by virtue of his inner resources alone, resources which must also motivate him to continue to keep up-to-date. In solo practice the burden of control rests solely on individual motivation and capacity.

Much more common than solo practice in the United States today is practice involving a loose network of interdependent practitioners who refer cases to each other—an informal organization that has been described as a "colleague network" (Hall 1946). Backed by a stable clientele relatively loyal to them, the practitioners in such a network control access to that clientele and thus access to work on the part of new young practitioners. In the rather well-organized case he studied, Hall showed how an "inner fraternity" of practitioners controlled access to practice settings and desirable patients and how, through the mechanism of sponsorship, newcomers were obliged both to take on minor tasks and to turn to their sponsors for consultation. While it may be doubted that professional services in large cities can be wholly dominated by any single informal fraternity, the sociometric studies of Coleman and his colleagues (1966) suggest that there are systematic and persistent patterns of interrelationships among practitioners even in so loosely organized a system as exists in the United States. These patterns of interaction suggest two of the most important prerequisites for control of the practitioner's performance by colleagues rather than by clients: by referring patients to each other, each practitioner has the opportunity to *observe* some of the other's performance; by being economically and technically interdependent, each practitioner has some leverage to *influence* the other's performance.

Finally, one may mention the less primitive structures of practice that are characteristic of some European countries and are represented in the United States by large group practices and university clinics. These are essentially bureaucratic organizations, although the variations in actual administrative detail are countless. We may point to one logically distinct type of bureaucracy that has

received some theoretical attention in the literature because of its systematic deviation from the classical rational-legal model of bureaucracy. It has been called *professional* bureaucracy, and it has been characterized as a form of organization in which the hierarchy of professional practitioners is set apart from the hierarchy of the administration itself or (as in many European countries) a form of organization in which all important positions of organizational authority are filled by professionals. In both cases, professional work is free from the exercise of the authority of nonprofessionals even though the working professionals are technically subordinates in a bureaucratic system and lack the freedom of the entrepreneur. The exact theoretical importance of such a logical construct and the degree to which it mirrors enough of reality to be useful are by no means clear, but by pointing to the bureaucratic elements of organization it does indicate that here, more than in other forms of practice, physicians are in a position of interdependence that implies opportunities to observe and to exercise influence over one another's performance. Of all the types of practice reviewed, the bureaucratic type provides the best opportunity for professional self-regulation. Indeed, this is the type exemplified by high-prestige academic institutions in the United States and elsewhere.

Analytical types of practice

Thus far, it has been suggested that there is a range of practice organizations, from purely individual practice to bureaucratically organized practice. To understand how colleagues or clients may gain access to observe and influence performance, it is useful to distinguish those features of practice which determine both the source and the content of control. In this way it becomes possible to analyze the differential significance in the division of labor of various forms of specialization. The lay client's perspective on the service he seeks differs from that of the colleague group of professionals: this may be taken as axiomatic. Let us therefore distinguish practices by the degree to which they are amenable to lay or colleague control. It is clear that two types of medical practice form the logical extremes of the medical division of labor. At one extreme is practice wholly dependent on lay choice for its existence: it may be called *client-dependent* practice. Such a practice survives by using its own resources to attract and satisfy a lay clientele. Since the client uses lay standards in deciding that he needs professional services and in evaluating the services he gets, the practice must conform to lay standards in order to be patronized. Furthermore,

when wholly dependent on client choice, the practice cannot be observed by colleagues, nor is its survival dependent on their cooperation. In consequence, all the pressure on the practice is toward conforming to lay rather than professional standards. At the other extreme is *colleague-dependent* practice. It does not attract its own lay clientele but, rather, obtains clients through the referrals of other colleagues. Thus, in order to survive it must honor the prejudices of colleagues, and so is likely to conform more to professional than to lay standards.

How closely do actual practices conform to these logical types? The logical extreme of client-dependent practice does not seem fully applicable to any professional practice, although the "independent" solo neighborhood or village general practitioner comes close to it. Also close are specialists who must attract a clientele directly and do not have to make everyday use of hospital facilities—for example, in urban areas in particular, some internists, pediatricians, ophthalmologists, and gynecologists. In these instances lay standards may be expected to have some force. Empirical examples of the logical extreme of colleague-dependent practices are easier to find in modern medicine. Specialists like pathologists and radiologists, for instance, are almost completely dependent upon colleague referrals and therefore have little need for such client-oriented techniques as a good bedside manner. Here, we should expect considerably greater pressure to honor colleague rather than lay or patient standards.

This typology is based on the division of labor within the profession and is therefore applicable to analysis of the control of performance of individual practitioners in any kind of organized practice, from solo to bureaucratic. It might be pointed out, however, that in bureaucratically organized practice it is frequently the organization as a unit, not individual practitioners, that attracts a clientele and that all practitioners in the organization are therefore dependent on it for their work. Insofar as the organization is of the "professional" type discussed above, this means that dependence on it is actually dependence on the colleagues running it. Encouragement to meet professional standards of performance will therefore be considerably stronger than encouragement to meet lay standards. And insofar as work is at once more visible and amenable to control in such an organization than in less well-organized forms of practice, it is here that we should expect to find the highest professional standards. Indeed, it is the general opinion of teachers of medicine in the United

States, Great Britain, and elsewhere that this is the case, although adequate evidence to test this opinion has not yet been gathered.

All else being equal, then, we may hypothesize that colleague-dependent practices, in which the physician's performance is observable to and his work dependent on colleagues, will also be most likely to conform to professional standards. Insofar as bureaucratic practice is colleague-dependent, the same conclusion may be drawn for it. But this conclusion masks several assumptions the truth of which is not self-evident: first, that colleagues will exert control over performance; second, that the mechanisms of control used by colleagues are effective; third, that standards are homogeneous throughout the profession. The remainder of this article will explore these assumptions.

Professional regulation

Variation in the organization of medical practice bears on such necessary conditions for the exercise of professional regulation as the observability of performance to colleagues and the structural vulnerability of the practitioner to control by colleagues. However, while observability and dependence are necessary conditions for the effective exercise of supervision, they are not sufficient. What is needed in addition is the willingness to exercise supervision and exert effective influence over performance. What slender evidence there is suggests that rather less influence over performance is exercised than the organization of practice actually allows, and that the little regulation which does exist has properties that establish and maintain organized differences in performance standards.

The basic property of the system of control that seems to exist in the United States is its reliance upon what Carr-Saunders and Wilson, speaking of British medicine, call the "boycott"—that is, the refusal by individual practitioners to enter into a referral or collaborative relationship with those of whom they do not approve (1933, p. 403; see also Hyde et al. 1954). This device does not control the boycotted person's behavior so much as it pushes him outside the boundaries of observability and influence, to practice as he wishes in the company of those with similar standards. There seems to be a certain reluctance to exert active influence over another's performance—a reluctance that results in avoiding him rather than in seeking to change him.

There is, unfortunately, little systematically collected empirical information bearing on the process of supervision and control among physicians. A study by Freidson and Rhea (1963; 1965) of a

large academically oriented group practice in the United States indicated that while performance was visible along the axes dictated by the interdependence of specialties within the over-all division of labor, each practitioner tended to keep his complaints about others to himself, so that what he could observe of others' performance in the division of labor was not transmitted to other colleagues. Since bits of information were scattered piecemeal through the colleague group, no really organized control of performance could be initiated unless a man behaved so outrageously as to personally offend everyone. Furthermore, attempts at control were largely individual and hortatory, and there were no control devices intermediate between remonstrance and outright ejection from the organization (the latter being the structural equivalent of the boycott). While the physicians studied were aware of the looseness of supervision and control in this ostensibly well-organized practice, they were inclined to feel it adequate and appropriate for ordinary circumstances.

Another American study (Goss 1961; 1963) is particularly instructive because it was done in a setting into which supervision was built. There were clear bureaucratic as well as professional supervisory responsibilities allocated through hierarchical ranks. The superior physician in the hierarchy had the right and perhaps even the obligation to review case records and evaluate case management. Furthermore, he had the right to give advice to subordinates about the way a case should be handled, even when advice was not solicited. However, even though the supervisor was officially responsible for the care given to patients in his unit and therefore had the formal right to order that certain procedures be followed for a case, he very rarely gave such orders. Instead, he gave advice, which incurred no obligation to obedience. The only obligation the subordinate had was to consider the advice in the light of his personal experience with and responsibility for the case. So long as he could justify his management of the case by reference to medical knowledge and his clinical experience, and so long as it was he who took personal responsibility for the outcome, he could reject the advice of his superior. In short, even here, where supervisory inspection of performance was routine, the exercise of control over performance was quite loose and permissive. If this is so in hierarchically organized practice settings, it should be even more the case in the informal, small-scale community practices that are far more common in medicine. Thus, we may say that the medical profession, which has gained freedom

from regulation by others, regulates itself in ways whose effectiveness is not self-evident. The analytical problem here is to understand what contributes to shaping this peculiar process of regulation and to point up its structural consequences.

Professional values

Obviously, when a social structure *permits* certain kinds of behavior but that behavior does not occur, we must explore the situation further to explain why it does not. Our first question might be why, in such a loose system, the physician does not routinely abuse his privilege. Here, the internalization of general professional values postulated by Parsons (1951, chapter 10) seems a plausible explanation. Parsons defines the professional as someone who is supposed to be recruited and licensed on the basis of his technical competence rather than his ascribed social characteristics; to use generally accepted scientific standards in his work rather than particularistic ones; to restrict his work activity to areas in which he is technically competent; to avoid emotional involvement and to cultivate objectivity in his work; and to put his client's interests before his own [see PROFESSIONS]. These normative expectations are intended by Parsons to apply to all professions, not only to medicine, since he treats the medical practitioner as the archetype of the professional. But it may be objected that the same expectations are applicable to all technical service occupations, not only to professions. Plumbers, too, are supposed to be recruited and licensed on the basis of achievement, to employ universalistic standards in their work, to be functionally specific and affectively neutral. And while plumbers are expected to make enough money from their work to gain a decent income (just as are physicians), they are not expected to do this by cheating the customer. Thus, such values constitute only the most general foundation of conscientiousness in occupational practice.

Our second question, however, may be more specific to the medical profession. Why, if it so conscientious, does it not exercise more regulation over its members' performance? Such an extraordinarily loose regulatory structure has been explained by Carr-Saunders and Wilson (1933, pp. 399-400) and by Parsons (1951, pp. 470-471) by reference to the character of professional work. Instead of a set routine, medicine requires the exercise of complex judgment; instead of caution, the taking of risks. Therefore, regulation can only be loose. But of all the old established professions medicine is the one most based on fairly precise and detailed scientific knowledge. Indeed, the practice of medi-

cine involves considerably less uncertainty than many other technical occupations. As the use of the doctrine of *res ipsa loquitur* in American courts implies, there are some very clear rights and wrongs in medicine, even if there are also some uncertainties, and these rights and wrongs have not brought forth any formal regulatory mechanisms from the profession as such (as opposed to concrete organizations like teaching hospitals, in which regulatory mechanisms do exist). Without denying that there is a degree of uncertainty, we must conclude that the precision possible in much of modern medicine and the trivial routine of much of everyday medical practice call into question the adequacy of explaining the peculiarly loose structure of controls to be found in the profession by reference to the character of its work. However, it may be that the peculiar nature of the work of the practicing professional encourages a characteristic *sense* of uncertainty that reflects considerably more special values than those described by Parsons.

One such value is that of independence, or autonomy, which is significant for physicians in countries as different as Finland and the United States. Insofar as this value refers to social and economic independence, it reflects the entrepreneurial and individualistic ideology of the bourgeoisie, who are the prime source from which physicians are recruited in virtually all industrial countries. Insofar as the value refers to technical or professional independence—that is, the freedom to practice one's craft without interference, advice, or regulation by others—it seems more closely related to a state of mind encouraged by the character of professional work.

The aim of the practitioner is not knowledge but action, and while successful action is the aim, the tendency is to assume that any action at all is better than none. Furthermore, to take action requires faith in oneself and even a will to believe in whatever one does instead of maintaining a skeptical detachment. Dealing with individual and concrete cases, the practitioner is inclined to emphasize indeterminacy rather than lawful regularity and to be radically pragmatic, relying more on the results he associates with his own actions than on theory. These seem to be the orientations that contribute to the emphasis on clinical experience mentioned earlier in connection with medical education.

Given that the work of the medical practitioner is with individuals and that it is believed to be based on individual clinical experience, it follows that responsibility for the work can be perceived only as individual and personal. In assuming that

responsibility, the practitioner does gain gratitude for success, but he also gains reproach for failure. Given the risk of blame, he evidences a certain sensitivity and defensiveness in the face of any outsider's evaluation of his performance. This defensiveness is manifested in imputing more uncertainty to the work than in fact exists and in insisting on using his own personal, clinical experience as the ultimate criterion for evaluating his own performance. Thus, collective responsibility for regulation is diminished, and the inclination to rely on individual responsibility and personal experience is augmented.

These, of course, are merely suggestions of the complex task that has still to be done in picking out and interrelating strands of what might be called the ideology of the practicing professional. Instead of dwelling on values of such generality that they have doubtful analytical utility for understanding the quality of professional self-regulation, sociologists should determine the specific values attached to different types of professional work. Such an approach would supply one of the critical elements for an adequate explanation of the peculiarities of professional organization.

Informal organization of the profession

Even without detailed information it seems possible to suggest that the notion of informal organization serves as a vital link between the formal structure given to the American medical profession by the national, state, and county medical associations (see Hyde et al. 1954) and professional performance in the concrete setting of medical practice. By focusing on the characteristic way in which practitioners assert control over each other's performance, one can delineate the relation of one local practice to another and the loose groupings of practices that both carve up a community and extend outside its boundaries. When these informal groupings and the mechanisms of control they express are seen to be intertwined with the formal structure of the profession as a whole, much more of the character of the profession can be understood than by reference to formal associations and codes alone.

Recalling that ordinarily the ultimate mechanism of control is the personal boycott, we can begin to indicate the informal structure of the profession by following out the implications of the boycott's operation on the interrelations of practitioners. Let us assume that individual practitioners are free to select the work they will undertake and to choose the colleagues with whom they will work in the division of labor. In this situation, control of professional standards is exercised largely by

willingness to work with one man and to exclude another. But since exclusion as such neither changes a man nor prevents him from working, one may assume that he will eventually find a circle whose standards are such that he is not excluded.

There is thus a tendency for the control process to develop a stable set of colleague networks or fraternities. Each network, by the nature of its creation, is fairly homogeneous within itself. Its members share about the same professional standards, participate in each other's work, and participate in, if not dominate, the particular organizations and practices in which they work. But while each colleague network is likely to be fairly homogeneous, many differences are likely to exist *between* networks by virtue of the process of selection and rejection that differentiates them into separate networks. Thus there is not only likely to be little interaction between many contiguous networks, but also marked differences in technical and normative standards and in the practices and institutions in which the members of each network participate.

In a structure of this nature there is comparatively little opportunity for those in one network to be very much aware of the existence of other standards; and even when awareness may exist, there is little leverage by which one network could influence another because each has severed connections with the other and is independent of the other. Since it is a segregating process that leads to and maintains such networks, and since the individual's behavior is less regulated by such a process than classified and assigned to a self-maintaining collectivity of like people, we can see how within a single profession, even one quite free of lay interference, organized variations in professional performance can occur. While there are certainly social links between adjacent fraternities in the form of practitioners with connections in both, it does not seem to require a very large city to find individual practitioners who know nothing about each other.

The characteristic control mechanism of professional regulation then, paradoxically operates to place offenders beyond the control of those who disapprove of their performance. Moreover, the informal organization of internally homogeneous colleague networks segregated from interaction with each other sustains, if not reinforces, the differences in standards between networks. Apart from civil suit, which is a nonprofessional source of control over practice, and regulatory devices established in the limited milieu of teaching hospitals, all that is left to concerned members of the profession in the United States is exhortation and,

it is hoped, instruction by means of articles in professional journals that may or may not be read and that, if read, may or may not be influential on behavior.

What has been suggested, in short, is that the disjunctive process of social control characterizing the concrete, everyday practice of American physicians creates an informal structure of relatively segregated, small circles of practitioners, the extremes of which are so isolated from each other that the conditions necessary for each influencing the other's behavior are missing. Furthermore, the mechanism of control that produces and sustains this situation is no aberration—rather, it is characteristic of the profession, an outcome of its organization and of the way it sees itself and its work. The consequence is that a single profession can contain within itself, and even encourage, markedly different ethical and technical standards of performance, limited in a very superficial way by the minimal standards imposed by selective recruitment, a basic core of training required for licensing, and the writings of the leaders of the medical profession.

Tasks of a sociology of medicine

The problems of analysis described in this article are not unique to the sociology of medicine but affect the sociology of professions in general. If they can be solved for medicine, we will have taken a long step toward solving them for all professions. The central problem here, as in the study of society in general, is social control. The problem is particularly important for the professions because by definition they are free of the controls common to most occupations. In addressing the problem of control, it was necessary to assess the role of the state and of politico-legal institutions, the manifest and latent functions of professional education, the organization of work, the control processes operating in work, and the norms or values that bear on the exercise of social control in work. The outcome of that analysis was the suggestion that a fragmented structure underlies the serene façade of unity and homogeneity implied by the notion of a single profession joined by common values and a community of identity.

To extend, correct, and refine such a trial analysis of the organization of medical work is one of the prime tasks of a sociology of medicine. In the course of extending it, one would be led quite naturally into a more detailed examination of another major problem of analysis: the client-practitioner relationship. This problem, too, might be seen as one of control. The practitioner wants the client to seek him out for professionally appropriate reasons,

without visiting quacks and without untoward delay. He wants the client to accept his recommendations and follow them scrupulously. In seeking compliance on the part of his client, the professional cannot always rely on his influence as an expert. The character of this influence and of practitioner-client interaction has barely been explored in other than psychological terms, and poses a challenge both to the taxonomy of types of social influence and to the conceptualization of social interaction.

Finally, we may mention a problem of analysis that has not yet received much attention—the role of the professional in creating and defining his own work. In the case of medicine (more than of law or religion) this analytical problem has been confounded by the reification of “scientific knowledge,” a viewpoint in which disease is taken to exist independently of human action and the physician is regarded as merely a diagnostician and therapist of what is objectively “there.” However, disease that exists independently of human awareness and action is irrelevant to the sociologist, while biologically nonexistent “disease” in which people believe is quite relevant. What is sociologically relevant is a social definition of disease or any other kind of deviance, not the biological fact or fancy. If this premise be adopted, then it follows that physicians are responsible for the social creation of disease in the course of “discovery” and diagnosis [see HEALTH]. It would follow, further, that in medical practice the social organization of work biases the way in which diseases are created and shapes the way in which patients are managed and even created by diagnosis. Thus, a major task of the sociology of medicine is to study the causes and consequences of physicians' conceptions of disease, showing how disease as a social object is created or formed by medical institutions (Scheff 1966). If this task should be performed as something independent of the conventional study of the process of scientific discovery, and with different premises, we will have come a long way toward understanding the social institutions of medicine as one of the modern professions.

PARAMEDICAL PERSONNEL

The term "paramedical" refers to occupations whose work is both organized around tasks of healing and ultimately controlled by the authority of physicians. Ultimate control by medical authority is manifested in a number of ways. First, much of the technical knowledge learned by paramedical workers during the course of their training and used during the course of their work tends to be discovered, enlarged upon, and approved by physicians. Second, the tasks performed by paramedical workers tend to assist, rather than directly replace, the focal tasks of diagnosis and treatment. Third,

paramedical workers tend to be subordinate in that their work tends to be performed at the request or "order" of, and is often supervised by, physicians. Finally, the prestige assigned to paramedical occupations by the general public tends to be less than that assigned to physicians.

The paramedical occupations may be distinguished from established professions by their relative lack of autonomy, responsibility, authority, and prestige. However, the fact that they are by definition organized around an established profession and in varying degrees partake of some, but never all, of the elements of professionalism allows us to distinguish them from many other occupations and, indeed, argue that they represent a sociologically distinct form of occupational organization.

Furthermore, it may be noted that paramedical occupations are not adequately distinguished by reference to their health-related tasks. Occupations usually called paramedical do participate in a functional division of labor, but what is distinct about this division of labor is that it is ordered by the authority of a prime profession. Other occupations which may actually perform some of the same technical tasks but which stand in a different relationship to the dominant profession (as does, for example, a herbalist compared to a pharmacist) are not called paramedical, but rather quack or irregular. Differences between the paramedical and the quack do not necessarily arise from the actual tasks each performs, but rather from the relations each has to the dominant profession. Thus, the paramedical worker is less easily distinguished technologically, by the relation of his work to that of others, than sociologically, by his relation to medical authority.

However, distinct as it is, this "paraprofessional" pattern is not common. For example, while there is a fairly elaborate division of labor revolving around law, it would not be appropriate to use the term "paralegal" for bailiffs, accountants, clerks, real estate brokers, and bankers in the same way that we use "paramedical" for nurses and laboratory technicians. Nor does the prefix seem properly employed to designate the division of labor connected with any other established profession. Medicine alone seems to have imposed such definite order on the occupations surrounding it. We can but guess the reasons for this, citing such variables as the comparative specificity and technical complexity of the tasks involved, which can only be exercised in a medical setting. Whatever the reason, this mode of organizing a division of labor is taxonomically distinct, and if it is true that labor is in general being "professionalized," the paramed-

ical model may become more widespread in the future. Both practically and conceptually it is worth close study. How did it develop? What are its present characteristics?

Development of the division of labor

A division of labor in the task of diagnosing and treating human ills has always existed in one form or another in every human society. There have always been diagnosticians, herbalists, midwives, and nurses, even if only on a part-time, amateur basis. However, the distinctive division of labor labeled paramedical—which is to say, one organized around the authority of the medical profession—is relatively new and is complex only in the highly industrialized societies of the world where the modern medical profession arose. Even in these countries it varies a great deal in the completeness of its integration around and control by the medical profession. Unfortunately, there are few adequate cross-national comparisons of the organization of health workers to provide even the basic descriptive information necessary for analysis, and so much of the indication of the types and sources of variation must be based on scattered bits of information (for one comparison, see Glaser 1966).

In Europe a distinctly paramedical division of labor, organized around the authority of a medical man, had begun to emerge at least by the time of the development in cities of the corporate guild and the university. The city provided the population density necessary for the support of a variety of *full-time* specialists, thereby allowing true occupations to arise. The guild provided the health-related occupations with a workable type of organization through which a distinct occupational identity, visible to officials and public alike, could slowly be established and through which they could press for exclusive rights to that identity and the work it involved. However, the right to have something of a monopoly of title and function—that is, to be licensed—and to control in a fairly strict way access into and progress through the occupational career was obtained from the state. Thus, the occupation gained organization, but it also became subject to assignment, by a political process, to a relatively well defined *official* position in a larger division of labor—a position that could involve enforced subordination to members of quite another guild.

The significance of the university in this situation is that occupations trained in one had a stronger claim, by virtue of their aura of learning and science, to a superordinate position in the occupational structure. University training gave phy-

sicians and surgeons a strong political position for persuading the state to subordinate to them such competitors as apothecaries, grocers, and barbers, and to allow them to prosecute irregular practitioners. This could be so even when it was doubtful that the actual knowledge and skill of the average university-trained practitioner in those days equipped him to practice any better than his self-taught or apprenticed competitor.

With the development of the university and the guild in European cities, then, there arose a rudimentary structure of full-time health workers, organized, at least in part, under the supervision of physicians and surgeons. For centuries this organization was highly unstable, weakened from within by undisciplined competition and from without by the persistence of a great variety of irregular practitioners (see King 1958; Turner 1959). As is the case with the health services in the nonindustrial countries of today, the medical division of labor was fairly stable only in those parts of cities where a well-to-do gentry was likely to patronize it. In the city slums and in the countryside the poor and the peasantry persisted in relying on their own folk remedies, their own, largely part-time practitioners, and, on occasion, itinerant irregulars; the first two being part of their own culture, the last exploiting the naïvete of that culture. There were in essence two health systems: the dominant one was rooted in the peasant culture, while the other, which was available only to a minority, owed its greater prestige to its origins in the learned traditions of Western civilization. Before the latter could become at once stable and universal, the former had to be destroyed or at least severely restricted. Not until the twentieth century in Europe and North America did anything emerge resembling a stable and extensive division of labor dominated by physicians, that is to say, a genuine paramedical division of labor. In the nonindustrial countries of the world today, such a structure does not yet exist to any great degree.

Modern developments. The prime prerequisite for the development of a stable and extensive division of labor that is distinctively paramedical seems to be the eradication of great qualitative differences in culture and education among the major social strata of a society. This seems to be so because health services are used mostly on a voluntary basis. People choose to use one health service rather than another, and if only one organized service is available, they can choose not to use it and rely on their own informal resources instead. In this sense, while the application of political power can drive out of practice all but officially li-

censed workers, it cannot make people use them. It seems no mere coincidence that the irregular health services declined greatly in industrialized countries about the same time that the institution of compulsory universal education arose. Contributory to this process, but by no means enough by itself (as experience in nonindustrial countries today indicates), was the rise of scientific medicine, which was capable for the first time in history of alleviating many complaints and symptoms consistently and predictably.

By the twentieth century the medical profession was at last able to establish a secure mandate to provide a central health service. In England the rural general practitioner had been drawn into regular medical ranks. In Russia the feldsher had been in part replaced by and in part subordinated to the physician. In the United States the many different kinds and qualities of practitioners, all democratically calling themselves doctor, had been reduced to some uniformity. Control over the focal tasks of diagnosis and prescription was thereby secured (Sigerist 1935), and by virtue of its major role as arbiter in the application of new scientific discoveries, the profession could order around itself the proliferating new technical personnel.

Some historical specialties, such as dentistry, survived fairly independently of the paramedical division of labor. Others, such as pharmacy and optometry, were not fully integrated into the paramedical division of labor, remaining at least partially independent of it. Still others, such as bone-setting and, in the United States, midwifery, were taken over by the physician himself, laymen and amateurs being driven out of practice. Others, the most prominent of which is nursing, maintained an ancient function while being brought firmly under medical control. And finally, with some few exceptions, such new specialties as laboratory technology, which arose with the new medical science and technology inside the walls of the hospital and medical school, developed unequivocally as part of an established paramedical division of labor.

Today's paramedical division of labor is therefore a specifically historical construction, with some *functionally* related occupations falling inside it and some outside it; not all of the very old or the very new occupations fall inside it. The source of whatever order may be found in this division of labor seems to lie in the character of the relationships to be found between medicine, other occupations, and prospective lay clientele—central to which, perhaps, is the possibility of functional autonomy.

Relations with the medical profession. The interoccupational relations of paramedical workers

can be seen clearly only as part of a larger, evolving structure that embraces physicians, health workers who are not part of the paramedical division of labor, and the institutions in which medical and nonmedical health services are provided. One of the major variables mediating interoccupational relations in the health services seems to be *functional autonomy*—the degree to which work can be carried on independently of organizational or medical supervision and to which it can be sustained by attracting its clientele independently of organizational referral or referral by other occupations, including physicians. On the whole, the more autonomous the occupation and the greater the overlap of its work with that of physicians, the greater is the potential for conflict, legal or otherwise. Such conflict is to be seen between chiropractors and physicians in the United States, homeopaths and physicians in the Soviet Union, and "native" practitioners and physicians in virtually all nonindustrial countries.

The most interesting conflicts, however, occur *within* the paramedical division of labor during the course of the growth of new occupations capable of attaining functional autonomy. In the United States, where the movement toward professional status is strong and extensive and there are not enough physicians to perform all the traditional functions demanded of them, such conflict is common; it focuses on the question of whether or not nonphysicians are to be allowed to offer health services independently of medical supervision. The outcome has been, in such increasingly successful cases as that of the clinical psychologist, virtual independence in practice, limited only by the legal inability to prescribe drugs. Impelled by the force of professionalization, the growth of new techniques and new occupations to practice them seems to be giving a new shape to the paramedical division of labor. Some years ago it could be visualized quite simply as a pyramid, with the physician at the apex. However, in the present-day United States the pyramid seems to be changing into a less clear-cut structure, at the top of which is a plateau along which are ranged physicians as well as other relatively autonomous, but consulting and cooperating, new professionals.

Recruitment and training

Obviously the paramedical division of labor is a stratified system, the occupations of which are in varying degrees integrated around the work of the physician. All occupations in the system are given less prestige than the physician by the society at large. It follows that the socioeconomic status of those recruited into all paramedical occupations is

likely to be lower than the status of those recruited into medicine itself. Furthermore, there is a hierarchy of prestige and authority among the ranks of paramedical workers; nurses, for example, are higher than attendants and technicians. This hierarchy is also likely to be reflected in the socioeconomic backgrounds of the workers. In the grossest comparison between physicians and paramedical workers, the latter are to a disproportionate degree women and from the less valued ethnic, racial, and religious groups. With the special exception of sex, those differences in background and personal characteristics are also likely to be ranged in an order corresponding to the general hierarchy of prestige and authority.

Variability of training. Training follows a variable pattern, its order roughly paralleling the prestige, independence, and imputed responsibility of the work (see Wardwell 1963). Patterns of training range from the one extreme of professional schools associated with universities, requiring a full higher education before several years of training, to the other extreme of brief, informal, on-the-job training. Between these extremes are many types of training, varied according to the length of study, the formality and abstractness of the curriculum, and the type of institutional arrangement, such as attendance at hospital training schools or proprietary technical schools, apprenticeships in various institutions, and the like. In the United States, where the university is a considerably less clearly defined institution than elsewhere, more paramedical education with professional trappings is to be found. In Europe technical training schools quite separate from the university are more likely to exist, for the education of even the high-prestige, more independent paramedical occupations.

The paramedical ranks tend to be ordered by the length and type of training required by the occupation: the longer the training and the more formal and the closer to the university it is, the higher is the occupation's position in the division of labor. It follows from this that the higher the position, the greater must be the investment of time and energy in training, the less casual can be the recruitment, and the greater must be the commitment to the occupation. Recruitment to the many low-skill positions in the paramedical division of labor seems, by and large, to be a simple function of the demand for unskilled service workers willing to do unpleasant work. Recruitment to the higher-skill positions, however, is considerably more problematic, especially in those occupations traditionally filled by women.

The position of women. Nursing is a fairly well-documented example of problems of recruit-

ment and training in the paramedical occupations (see Corwin & Taves 1963). The problem in nursing is not that of attracting people to undergo training as such, for quite a few women begin training; it lies in recruiting women who will stay in training and subsequently pursue a lifetime career in the occupation. The essential difficulty here is that women are likely to be torn between the commitment to work and the commitment to marriage and family. This conflict has been discerned in nursing students and seems to be closely related to school dropouts and subsequent job turnover.

Leaders of nursing in the United States have attempted to contend with the problem by emphasizing the professional qualities of the occupation, presumably hoping to create a stronger "professional" commitment to work that might outweigh family considerations (Strauss 1966). The problem, however, seems to be inherent in the position of women in the labor force and does not seem soluble by professionalization. Even in the case of that most professional of professions, namely medicine, only a modest proportion of women in the United States who are qualified to practice medicine actually do so. One might therefore suspect that a more likely solution for a social system such as that of the United States would be found in changing the organization of the job so as to accommodate it to the demands of marriage and family.

In European countries the position of women in the medical and paramedical labor force is quite different, apparently because of national differences in the occupational roles of women that make a professional career highly desirable among women of the *haute bourgeoisie*, small but significant differences in the class system, and, finally, the level of industrialization and the general standard of living. The last consideration brings up another aspect of recruitment and training in the paramedical division of labor. Clear evidence is lacking, but general opinion seems to be that it is becoming more and more difficult to recruit people to the paramedical jobs that require considerable investment of time and money in technical training. If this is so, it might be understood as a symptom of a larger process of advanced industrialization.

Emphasis on professionalism. In the earlier stages of industrialization, the health services constituted a major and conspicuous source of social and economic mobility to which those willing and able to invest in specialized training could aspire. However, in later stages the demand for skilled technical services has developed markedly

in other segments of the economy, thereby providing a considerably wider universe of opportunity than that which existed earlier. As older, fairly closely organized systems, requiring relatively extensive investment in training but offering relatively inflexible career lines, the health services, medical as well as paramedical, seem handicapped in competing for a limited pool of potential workers. Part of the pervasive emphasis on professionalism within the paramedical division of labor in the United States seems to be an attempt to increase the attractiveness of the work and thereby aid in recruiting the best possible workers.

However, the emphasis on professionalism is likely to be strong only during the course of training, which is where the leaders of the occupation are most likely to be influential. Inasmuch as professionalism tends to emphasize intellectual and technical skill, there is the danger of dissatisfying students whose motives for entering the occupation are not so much intellectual as humanitarian—a danger that has been observed in nursing schools. Furthermore, inasmuch as professionalism tends to emphasize the dignity and autonomy of the worker, it is likely that upon leaving school and entering the everyday institutions of work, which are generally not controlled by the leaders of the occupation, the erstwhile student, who has been imbued with professionalism, is in for what has been called "reality shock." If the student's indoctrination has been thorough, his relations with other occupations in the paramedical hierarchy are likely to be somewhat difficult and personally disillusioning.

Paramedical personnel in the hospital

It has been implied that the greatest opportunity for developing functional autonomy seems to exist for those occupations that can operate outside the walls of such medically organized institutions as clinics and hospitals. The nursing profession, whose leaders in the United States have with great energy sought to establish unique skills and fully professional status, seems fated nonetheless to remain subject to the doctor's orders, in part because a nurse's work is largely carried out in the hospital. In this, however, the nurse is not unique: the largest part of the paramedical division of labor grew up within such organizations and may be expected to persist and proliferate within them in the future. It is for this reason that once we leave the broad societal level of analysis of the paramedical division of labor to undertake the analysis of everyday work, we find ourselves

in the community agency, the clinic, and, most extensively studied of all, the hospital.

All hospitals are complex organizations coordinating a number of tasks and forming the focus for a number of distinct, usually overlapping goals. Given the fact that hospitals are fairly stable and spatially fixed, it is no accident that the paramedical occupations working within them have been studied far more than those working outside in the community at large, where the bulk of health services are actually provided. Thus, we have a severely limited view of paramedical as well as medical work. Among studies of hospital personnel, the nurse in the general hospital is the most frequent subject, and the attendant or aide in the mental hospital ranks second. We have little systematic empirical information about virtually all other paramedical workers. Handicapped as we are, the nurse and attendant between them do present us with a view of the range of workers, from the most professional to the least. By reviewing their respective positions, we can obtain some hints about the kinds of analytical problems posed by the work of paramedical personnel.

The nursing profession. It is difficult to speak of nursing as a single occupation, because the training and work situations of nursing are so variable. Training in the United States can vary from a three-year hospital-nursing-school program to a four-year college program and even to programs leading to the doctorate (Davis et al. 1966). On the job, nurses in some American and European hospitals are preoccupied with bedside patient care and virtually all housekeeping tasks; however, in larger American teaching hospitals nurses are characteristically engaged in supervising the lesser personnel who give bedside care and do the housekeeping. Furthermore, there are major differences in the organization of hospitals in which nurses work: in most hospitals throughout the world the medical staff constitutes the only significant hierarchy, but in some of the larger American hospitals the medical hierarchy is paralleled by that of a nonmedical administrative staff. In the latter case the nurse's traditional subordination to the physician becomes complicated by subordination to another hierarchy. The two lines of authority may make quite different, even opposing, demands on her, thereby introducing into her work more strain than has existed traditionally (see Croog 1963).

However, the problem of two lines of authority in hospitals has been overemphasized, particularly in light of the fact that the development of an administrative hierarchy provides the nurse with a

better opportunity for mobility than exists when a medical hierarchy alone is present. The possibility of moving up into an administrative hierarchy is common for many occupations, including medicine, but it seems particularly significant for para-professional occupations. By their nature such occupations are technically subordinate: success within the occupation does not remove that subordination, and movement into the superordinate occupation is not usually possible. Only by forsaking the particularistic skills of the occupation and moving into administrative positions can that subordination be escaped. While administrative positions may in fact not be superordinate to professional staff positions, they may at least run parallel to the professional positions and attain equality with them.

We can therefore understand why it is that nurses who are preoccupied with attaining a fully independent status attempt to pass over as "dirty work" the skills of bedside care (i.e., what was once called nursing) to lesser workers and to specialize in administrative work (see Hughes 1958). Recalling the problems involved in recruiting students who can become committed to nursing as a career and the attempt to create such commitment by emphasizing professionalism, we are led into an interesting dilemma: if women become committed to nursing by becoming "professionalizers," their commitment makes them prone to forsake the work for which they were recruited in the first place.

That dilemma, however, is more characteristic of nursing in the United States than elsewhere, reflecting a national emphasis on social mobility and professionalization. Furthermore, it refers to one of the better-established paramedical occupations and more particularly to those members of the occupation in the United States who have been trained in and work in the high-prestige, academically oriented institutions. As such, it is hardly representative of the total range of paramedical occupations and their dilemmas. The cross-national comparison presented by William Glaser (1963) suggests that the more common problems of paramedical occupations are not really represented by American nursing studies. What is needed most is insight into the less trained, less mobile occupations. Unfortunately, about all we have to provide us with this insight are studies of attendants and aides in American mental hospitals.

The attendant. The essential problem posed by the hospital attendant, and presumably by other relatively untrained personnel in similar positions in the division of labor, is his failure to satisfy

the expectations of his professional supervisors. This difficulty may be the more important because the attendant is in the most continuous and intimate contact with the patient and therefore may in fact have greater influence on the patient than the supervising professionals. Thus, his "custodial" orientation to his patients is deplored, and a more "therapeutic" orientation is expected.

The cause of the attendant's deficiencies seems to stem from at least two sources. First, his job is, in the most immediate sense, one of keeping order—minimizing dirt, destruction or waste of property, and personal injury and allowing house-keeping, therapeutic, and other services to be carried out on a predictable and efficient schedule. In the nature of the case this is a custodial responsibility, requiring something of a custodial attitude. If health institutions are to be run relatively economically, such an attitude on the part of those responsible for the hour-by-hour care of resident patients seems necessary and inevitable.

It is the second element that is more variable—the way in which the attendant perceives his patients, their illness, and his relationship to them. Almost by definition, as a paramedical worker without formal training, the attendant is likely to adopt a view similar to that of the layman. The problem is not lay attitudes as such but *which* lay attitudes the attendant adopts. A great many studies of American state mental hospitals suggest that attendants adopt an attitude of punitiveness and contempt toward patients and of antagonism toward the expectations of the professional staff. Part of this attitude, as noted already, stems from the job the attendant has to do, as well as from the feeling that the more remote professional staff does not really understand how difficult it is to keep order or even how to keep order. Another part, however, seems to reflect more than anything else the average "unenlightened" American layman's conception of the mentally ill (see Strauss et al. 1964).

Attendants from other cultures may have entirely different conceptions of the mentally ill and behave quite differently, as Caudill's analysis of the *tsukisoi* in Japan (1961) and Parsons' discussion of a Neapolitan hospital (1959) suggest. Even in the United States, when the illness involved is not as stigmatized as mental illness, lay attitudes of unskilled aides can be supportive rather than punitive, sympathetic rather than hostile. In this sense, precisely what is "unprofessional" about such lower-order workers can be as much a virtue as a vice.

Indeed, that same less-professional character

enables the paramedical worker to accomplish what the professional cannot, that is, the paramedical worker can draw into treatment patients who would otherwise be evasive and hostile to organized health services. Many studies from around the world, particularly those summarized by Simmons (1958), indicate that patients of humbler origins than that of physicians feel more comfortable dealing with such paramedical workers as nurses, fieldshers, and midwives, who are closer to their own class and culture. Furthermore, lower-status patients seem more easily "educated" by paramedical personnel than by physicians, not only because they can enter into rapport more easily but also because they are more prone to "speak the same language" and to adjust themselves to the patient's expectations.

This lesser social distance from patients seems to be particularly critical in circumstances where the contact between patient and health worker is voluntary and casual, rather than forced and desperate, and where status differences are quite marked, linguistically, culturally, and socially. Indeed, it appears that it is the need on the part of lower-status patients for consultants who are more nearly equal to them and who operate in a manner compatible with their culture that modern irregular practitioners have risen to serve. To the extent that paramedical personnel become professionalized, they may lose their advantage in dealing with lower-status patients. However, to the extent that the paramedical worker's success with those patients is predicated on lay attitudes, his relations with supervising professionals are certain to be problematic. This is one of the major dilemmas of paramedical work.

MEINECKE, FRIEDRICH

Friedrich Meinecke (1862–1954) was the most important German historian to follow Ranke and Burckhardt. He developed Dilthey's concept of history of ideas; he followed the philosophy of historicism, first outlined by Ernst Troeltsch and Benedetto Croce, to its logical conclusion; and finally, he achieved a synthesis of historical thought and political action by becoming one of the moral leaders in Germany's return to democracy after 1945.

Sources of thought. Meinecke was born in the town of Salzwedel in Prussian Saxony but was brought up in Berlin in solid, middle-class surroundings. As a student, he was stirred by the personality of Bismarck and influenced by the sense of discipline and courage found in the Prussian state. But Meinecke was impressed by the classical humanism of German literature and music, poetry, and philosophy as well as by the spirit of Potsdam.

After leaving the Gymnasium, Meinecke entered the University of Berlin, determined to become a historian. There he was initiated into the techniques of historical methodology which Leopold von Ranke and his school had perfected. Meinecke accepted not only their methods but also their general frame of reference; i.e., that the proper subject of study for the historian is conflict among the great powers. He attended the lectures of Johann G. Droysen and Wilhelm Dilthey; Heinrich von Sybel and Heinrich von Treitschke directed his scholarly pursuits.

A speech defect from which he suffered throughout his life made Meinecke choose the career of secluded archivist rather than academic teacher, and in "this dusty trade" he felt at home for many years. Among his fellow archivists was one of the masters of institutional and comparative history, Otto Hintze, who exercised considerable influence on Meinecke. Although Meinecke was shy and withdrawn by nature, his special gifts were soon recognized. In 1893 he was asked to become editor of the *Historische Zeitschrift*, Germany's most important historical review.

History of ideas. In these early years of apprenticeship, Meinecke was already concerned with the world of political ideas. He formulated the task of the historian in this manner: "Ideas, carried and transformed by living personalities, [constitute] the canvas of historical life" (*Erlebtes* . . . p. 117). This sentence represents the core of Meinecke's *Ideengeschichte*. He first put this conviction to the test when he wrote the biography

(1896–1899) of Hermann von Boyen, the Prussian minister of war who, in 1814, introduced military conscription. It was a pioneering attempt to make the arid facts of military history a part of the history of ideas.

Meinecke's biography established Boyen's niche in history and Meinecke's own reputation as one of the most promising talents in Germany's academic world. His appointment as professor of modern European history at Strasbourg in 1901 was evidence of his immediate recognition. There, in the southwestern corner of Germany, Meinecke encountered some of the best minds then active in that country: Max Weber, Ernst Troeltsch, Heinrich Rickert, and many others, and they made him aware of the limitations of his earlier perspectives. One of Meinecke's characteristics was his never-failing capacity for growth; in Strasbourg, and after 1908 in Freiburg, he shed much of his Prussian parochialism.

For more than a decade Meinecke remained fascinated by the problems and paradoxes of German history, especially the years from 1789 to 1848. In his next work, *Weltbürgertum und Nationalstaat* (1908), he endeavored to show how cosmopolitanism and nationalism had become deeply intertwined in the complex development of nineteenth-century Germany. He showed how both elements could be found in the ideas of Fichte, Novalis, Schlegel, Hegel, and Ranke, and how early German nationalism was made up of politically inconsistent cultural components. As Meinecke saw it, the universalistic tendencies of German thinkers were put to the test in 1848, and the revolution failed because of the incapacity of many Germans to come to grips with the realities of power politics. In this perspective, Bismarck and what he stood for became essential to the German quest for national unity. Hegel, Ranke, and Bismarck were the great liberators who freed the German mind from its romantic mists and created a realistic attitude toward the state.

Meinecke thus traced the philosophical and literary origins of the ideology of the nation-state and went beyond the traditional borderlines of political history. His works were soon recognized as masterpieces in a new field, the biography of ideas or, as it were, of two ideas. He was at his best when analyzing the major polarities in Western thought: order and freedom, nationalism and universalism, power and ethics, "is" and "ought," uniqueness and recurrence. He became the historian of political ideas par excellence, founding a new school of historical thought, and developing a unique style—

subtle, sensitive, and highly expressive of the countless variations and mutations which political ideas produce as they develop.

In Freiburg, Meinecke moved into the political arena for the first time. Abandoning the conservative leanings of his earlier years, he joined the right wing of the liberal party, the National Liberals. His goal was the widening of the foundation of the nation-state to include the ever-growing masses of industrial labor. His initial attempt was timorous and lacking in energy; he approved of representative government, not as an end in itself, but as a means to an end—that of enabling Germany to play her role as a world power.

The nature and justification of power. In 1913 Meinecke accepted an appointment at the University of Berlin. At the outbreak of World War I he was at first uncritically committed to Germany's imperialistic aspirations. Only slowly did it dawn on him that this conflict harbored consequences surpassing by far the significance of previous engagements between feuding European nations. As the horizon around Germany grew darker, however, Meinecke's perceptions became more piercing. His keen political analysis and counsel, in turn, began to be sought after by the more thoughtful statesmen of Germany; Richard von Kühlmann, secretary of state in the Foreign Office, and Theobald von Bethmann-Hollweg, the hapless chancellor, discussed with Meinecke the unsolved problems of Germany's domestic situation and the chances for a negotiated peace. He began to work for a peace by compromise and without territorial gains for any of the great powers. He also bent his efforts toward more equitable political representation for the working class. But although his advice was heard in many quarters, it was little heeded.

More important than Meinecke's remedies for specific problems, however, was his emergent comprehension that the nation-state in which he had so strongly believed was no longer a sufficient answer to the political exigencies of the twentieth century. New questions crowded his mind: what was power? what was Germany's relationship to the rest of the Western world? what lay behind the great conflict that seemed to be splitting the Occident? Meinecke could not accept the Marxist-Leninist interpretation of the crisis, since world revolution and the revolt of the masses appeared to him as the predominant threats to Western civilization. On the other hand, by the time the war ended he realized that the old, aristocratic Germany was doomed. The downfall of imperial Germany in 1918 filled him with grief but not with despair. He

accepted the Weimar Republic as a necessity and was ready to work for a new democratic Germany.

Meinecke's doubts about the nature and justification of power, aroused by World War I, were crystallized in his book *Machiavellism* (1924). Meinecke admitted that it was the extreme manifestations of power politics during World War I that had opened his eyes to the dangers of politics divorced from any ethical code. The Treaty of Versailles only served to deepen the lesson; it led him into a historical investigation of theories of the nature and function of power in human life, beginning with Machiavelli, through Bodin and Rohan, to Frederick the Great, Hegel, Ranke, and Treitschke. There are those who consider the book to be a history of Machiavellianism; others view it as an attempt to surmount the teachings of Machiavelli. Neither of these interpretations hits the mark; more nearly, the book is Machiavellianism considered with a guilty conscience. Meinecke could not subscribe to Burckhardt's and Acton's thoroughgoing condemnation of power; neither could he any longer assent to the idolatry of power found in Hegel and Treitschke. The result is a dichotomy, a separation of ethics and power that defies reconciliation: the creed of the statesman, said Meinecke, must embody both the interest of the state and the fundamental moral principles of mankind.

Historicism. There is a mood of philosophical reflection in *Machiavellism* which foreshadows an even more complex enterprise—a study of the genesis of historical thought. In Berlin, Meinecke lived in close contact with Troeltsch, who considered the historical outlook in its most comprehensive sense as characteristic of the twentieth century. In 1922 Troeltsch published *Der Historismus und seine Probleme*. After Troeltsch's death in 1923, his work on this subject was continued by Meinecke. However, Meinecke's perspective was somewhat narrower: as a historian he was more interested in the origins of historical thought than in its significance for the future of Western civilization. In 1936 he published *Die Entstehung des Historismus* ("The Origins of Historicism"). It is the third of his significant contributions to the history of ideas, completed when Meinecke was well past his seventieth year but dating back to very early reflections on the element of individuality, or uniqueness, in historical life.

German historians had long been hostile to positivistic attempts to reduce human development to "scientific laws"; such attempts, they contended, violate two of the most precious elements in his-

tory: spontaneity and uniqueness. Meinecke shared this interpretation of human life and traced it from the late seventeenth century to the twentieth. He defined "historicism" in the following manner: "the essence of historicism consists in replacing a general and abstract contemplation of human affairs by an individual one" (*eine individualisierende Betrachtung*) ([1936] 1959, p. 2). He did not hesitate to call this concentration on uniqueness the highest achievement in the contemplation of things human. This was an extreme stand, denying both the sociological ideal-type (as Max Weber conceived it) and the ethical norm of universal validity.

Die Entstehung des Historismus begins with an analysis of Shaftesbury, Leibniz, and Vico; it moves into an evaluation of the historiography of the Enlightenment, with special emphasis on Voltaire, Montesquieu, Hume, and Gibbon. From English preromanticism it switches to Möser, Winckelmann, Herder, and Goethe, and it ends with an epilogue on Ranke. Critics have pointed out, with justice, that this history of historicism ends at the moment when the movement really came into its own and that it describes its growth but not its flowering. Likewise, the problem of relativism (inherent in the idea of uniqueness) versus absolute and perennial values is stated by Meinecke but by no means elucidated or solved. Nevertheless, the book marks an important advance in the long discussion among historians, social scientists, and philosophers of the proper subject and the meaning of history.

The German catastrophe. Meinecke might have tried to answer some of these questions more conclusively had it not been for the general conditions of his time. When this book on historicism was published, Hitler had triumphed in Germany. Meinecke had fought with courage against the rise of National Socialism, both in the press and from his chair at the University of Berlin. Some of his close associates were ousted and silenced. Many of Meinecke's students were obliged to flee the country, and in 1935 Meinecke relinquished the editorship of the *Historische Zeitschrift*. But he was perhaps most oppressed by the foreboding of a second world war. His correspondence clearly reveals that he was one of the few German scholars who never compromised with the authorities and who had the courage to state frankly in his letters what he was not allowed to say in public.

An indefatigable worker, Meinecke spent these years working on his memoirs; they hold a certain charm but do not rank with his contributions to

intellectual history. The war did not spare him: he suffered the same privations, the hunger, and bombings, as millions of others. Finally he fled from Berlin, shortly before it fell to the Russians. Once more his mind turned to the enigma of German history, especially to the questions that have puzzled so many observers: how could the advent of Hitler be explained? and further, to what extent was Germany responsible for the greatest retrogression in European civilization since the days of the Black Death?

Meinecke's answers were given in a small book, *The German Catastrophe* (1946). He began his analysis with the statement that National Socialism must be understood against the background of our entire Western civilization, against the conflict between the old society and the new industrial masses. And he did not spare those forces which had once elicited his praise: the Prussian state and the German bourgeoisie. The Prussian state, he wrote, had permeated the nation with its militaristic attitude; the bourgeoisie had closed its mind to democratic forms of government, which alone could have brought a reconciliation between itself and the working class. He accounted for the success of a demonic figure like Hitler by indicating the German social interests which had tried to manipulate the "revolution of nihilism" only to become its victims.

This new approach, an attempt to combine intellectual and social history, is also apparent in other essays that Meinecke wrote after 1945, especially in his comparison of Burckhardt and Ranke (1948a) and in his appraisal of the revolution of 1848 (1948b). They reveal, if nothing else, an indomitable will to continue the task of the historian in a world changed beyond recognition from the well-grounded security into which Meinecke had been born.

When a large part of the student body revolted against the oppression of the communist-controlled University of Berlin, it found in Meinecke the leader to head an independent institution—the Free University of Berlin. To have heralded and ushered in so momentous an action is surely one of Meinecke's titles to lasting fame. His contributions to modern historiography have proved surprisingly durable and have reached well beyond the confines of Germany. They have been emulated, corrected, and improved in Austria, Italy, and, more especially, in the United States, where some of his students carry on his work.

MENGER, CARL

Carl Menger (1840–1921), economic theorist and founder of the Austrian school of marginal analysis, was both the most influential and the least read of the major figures who gave economic theory the shape it preserved from about 1885 to

1935. There is little doubt that it was his immediate disciples who cast microeconomic theory into the form which, in its essentials, it still retains. Of the three founders of modern utility analysis, he alone not only based his work on a long tradition and presented the outlines of his theory in a form which for some time could not be bettered, but also succeeded in creating a school which continued to develop his ideas. Menger exerted a widespread influence, mainly through his avowed disciples in many countries, despite the fact that his two main books were not reprinted for 50 years or translated into English for 79 years. His work also had an effect on the only important rival school of the period—the neoclassical Cambridge tradition. At an early stage, Alfred Marshall, founder of the Cambridge school, had evidently studied Menger's work much more assiduously than is suggested by the few references to Menger (most of which were dropped from later editions) in Marshall's *Principles*. (Marshall's personal copy of Menger's *Grundsätze*, with a detailed marginal commentary in Marshall's hand, is preserved in the Marshall Library at Cambridge.)

Menger was born in Neu Sandec, Galicia (then in the Austrian part of Poland), the descendant of a professional family that had earned the prefix "von" (Menger himself dropped it in early adulthood). In the well-stocked library of his father, a practicing lawyer, Menger and his two brothers became acquainted early with the literature on social and economic questions; one brother, Anton Menger, was a legal philosopher and historian of socialist doctrine.

Menger studied law at the universities of Vienna and Prague and finally took his doctorate at the University of Cracow in 1867. Apparently he had done some journalistic work in Vienna and Lemberg before taking the degree, and afterward he entered the press section of the prime minister's office in Vienna, a position which was frequently a springboard to high public office. In that position, apparently as a result of having to write market reports, Menger developed an interest in price theory. The recent publication of his annotations to Rau's *Grundsätze der Volkswirtschaftslehre* ([1870] 1963) suggests that it was mainly his critical analysis of this textbook exposition of classical doctrine that led Menger, from 1867 on, to develop his own value theory. In his extensive reading, Menger must have found ample material in the early nineteenth-century German and French economic literature on which to build a fully developed utility analysis. (The utility tradition was not as strongly preserved in the English literature.) It now

appears that the literature on which he was able to draw included also the work of an Austrian economist, J. Kudler (whose textbook, *Die Grundlehren der Volkswirtschaft* 1846, he had probably used at the university), and one work by Cournot. Menger's sources, however, did not include the work of the author who had the most completely anticipated him, Gossen's *Entwicklung der Gesetze des menschlichen Verkehrs* . . . , published in 1854.

The results of Menger's studies appeared in his *Principles of Economics* (1871), the work on which his fame mainly rests. Described as the "first, general part" of an intended comprehensive work on economic theory, it remained his sole major publication in this field during his lifetime. In somewhat copious but always clear language, it provided a much more thorough account of the relations between utility, value, and price than is found in any of the works of Jevons and Walras, who at about the same time laid the foundation of the "marginal revolution" in economics.

The book gained for Menger first a lectureship and, in 1873, the position of extraordinary professor at the University of Vienna. For some years he published nothing more, apparently because of his appointment in 1876 as tutor to the 18-year-old crown prince of Austria, the ill-fated Archduke Rudolf. For two years Menger accompanied Rudolf on extensive travels through Germany, France, and the British Isles. He seems to have assisted the crown prince in the composition of a pamphlet (anonymously published in 1878) which attempted a critical examination of the role played by the higher Austrian aristocracy. The pamphlet caused some stir when in 1906, 17 years after the death of the archduke, his authorship was discovered.

The real beginning of Menger's long and very effective career as a teacher came with his appointment in 1879 to a full professorship at the University of Vienna. During the next 24 years he expended most of his energy on his general lectures to law students (which he appears to have rewritten every year), and he was particularly attentive to those few students who voluntarily chose economics as their field of special work. His teaching was interrupted only twice by bursts of literary activity. The first of these was connected with his second major book, *Problems of Economics and Sociology* (1883). Here he undertook to vindicate the importance of theory in the social sciences. This was an effort that seemed necessary to him in view of the complete indifference or even hostility which most of his German colleagues, influenced by the antitheoretical attitude of the "younger historical school" in economics, had shown toward his

attempt in the *Principles* to reconstruct economic theory.

To understand the aim of the *Problems* and the nature of the great controversy to which it gave rise, it is necessary to appreciate the character of the school against which it was directed. The "younger historical school" is somewhat misnamed: unlike von Savigny and the older historical school of jurisprudence, or even Roscher and the "older historical school" in economics, this "younger" school was not interested in history as the study of unique events but regarded historical study as the empirical approach to an eventual theoretical explanation of social institutions. Through the study of historical development it hoped to arrive at the laws of development of social wholes, from which, in turn, could be deduced the historical necessities governing each phase of this development. This was the sort of positivist-empiricist approach which was later adopted by American institutionalists (differing from similar, more recent efforts only in that it made little use of statistical technique), and which is better described (as by Popper) as historicism.

It was against this use of history as a means of discovering empirical laws that Menger undertook to defend what he considered to be the proper function of theory—reconstructing the structure of social wholes from their parts by the procedure called methodological individualism by Schumpeter, or the "compositive method" by Menger himself. It is essentially what today is called microtheory. Menger was greatly interested in history and the genesis of institutions, and he was anxious mainly to emphasize the different nature of the task of theory and the task of history proper and to prevent a confusion of their methods. The distinction, as he elaborated it, considerably influenced the later work of Rickert and Max Weber. Perhaps the most important part of his discussion was the clear recognition, first, that the object of all social theory is the tracing of what are now usually called the unintended consequences of individual actions (Menger's term was the *unbeabsichtigte Resultante*), and, second, that in this effort the genetic and the functional aspects could not be separated ([1883] 1963, pp. 163, 180, 182, 188). In expounding and illustrating this view he went far beyond the limit of economics and dealt particularly with the genesis of law.

The nature of the dispute has often been confused by the fact that Menger, in arguing against what he regarded as the dominant pseudohistorical school in economics, maintained ideas which had reached him through the historical school in law.

These ideas can be traced back to Mandeville, David Hume, and the later eighteenth-century Scottish philosophers, although the degree to which Menger was directly acquainted with these eighteenth-century sources is not clear. It is worth noting that Menger always had a great interest in the history of economic theory and used it with much didactic skill in his lectures as an introduction to the problems of modern economic theory.

The *Problems* was unfavorably and condescendingly reviewed by Gustav Schmoller, the head of the younger historical school of economists; Menger replied to Schmoller's criticism in a passionate brochure, *Die Irrthümer des Historismus in der deutschen Nationalökonomie* (1884). This was the beginning of the celebrated *Methodenstreit* (dispute on method). Emotions ran high; younger men on both sides joined in; and the dispute produced a cleavage between German and Austrian economics, traces of which were to be felt for decades. In a number of articles during the following few years Menger dealt mainly with problems arising out of the dispute, except for his only other contribution to pure economic theory, the article "Zur Theorie des Kapitals," published in 1888 (see *Collected Works*, vol. 3, pp. 133-183).

Menger emerged a second time from his academic seclusion in 1892 to join the discussion on the reform of the Austrian currency. His active participation in discussions of policy was foreshadowed in the very same year by his article on money (see *Collected Works*, vol. 4, pp. 1-2) for the new German encyclopedia of political science. The article was itself a substantial treatise, which devoted much space to the evolution of money but also emphasized the factors determining the amount of money held by individuals, and which laid the foundations for a theory of the value of money on which later Austrian economists, such as Wieser, Von Mises, and Weiss were able to build. No less important, however, are his memorandum and his oral evidence to the Austrian currency commission and various articles which he published in 1892 and in the next few years.

But while such special occasions led Menger to literary production, his teaching appears to have precluded progress on the great treatise which he hoped would replace his first work. Therefore, in 1903, he prematurely resigned his professorship in order to devote himself entirely to this task. But although he continued to work on it during the remaining 18 years of his life and at one stage seems to have come close to his goal, he continued his efforts after his powers had begun to fail, with the result that he left nothing that was readily

publishable at his death. His son included part of the manuscript material in a second edition of the *Grundsätze*, which appeared in 1923. But the publication of more of the manuscript material has proved to be a very difficult task which so far has not been accomplished.

Menger built up over the years one of the greatest private libraries in the field of social science, which in 1911 he estimated at something like 25,000 volumes. The sections dealing with the social sciences and anthropology were sold after his death to the Commercial University (now Hitotsubashi University) in Tokyo, which published a catalogue of it in two parts, one in 1926 and the other in 1955.

In an assessment of Menger's influence it should be noted that his ideas were introduced into anthropology by Richard Thurnwald, one of his students.

MENTAL DISORDERS

General considerations underlying the study of mental disorders are discussed in the articles under this heading. Concepts of direct relevance are also discussed in ANXIETY; DEFENSE MECHANISMS;

STRESS. General categories of mental disorders are reviewed in the articles NEUROSIS; PSYCHOSIS; specific disorders are discussed in CHARACTER DISORDERS; DEPRESSIVE DISORDERS; HYSTERIA; OBSSSSIVE-COMPULSIVE DISORDERS; PARANOID REACTIONS; PHOBIAS; PSYCHOPATHIC PERSONALITY; PSYCHOSOMATIC ILLNESS; SCHIZOPHRENIA. Methods of assessing mental disorders are discussed in ELECTROENCEPHALOGRAPHY; INTERVIEWING, article on PERSONALITY APPRAISAL; PERSONALITY MEASUREMENT; PROJECTIVE METHODS. The treatment of mental disorders is discussed under CLINICAL PSYCHOLOGY; COUNSELING PSYCHOLOGY; INTERVIEWING, article on THERAPEUTIC INTERVIEWING; MENTAL DISORDERS, TREATMENT OF; PSYCHIATRY; PSYCHOANALYSIS. Social problems that can be considered as aspects of mental disorders are discussed in DRINKING AND ALCOHOLISM; DRUGS; SEXUAL BEHAVIOR, articles on HOMOSEXUALITY and SEXUAL DEVIATION; SUICIDE.

GENETIC ASPECTS

People who are related to one another by blood tend to resemble one another in, among other things, their mental make-up and their liability to mental illness. Both genetic and environmental factors may play a part in this resemblance. The most widely accepted view of the nature of the interaction between heredity and environment has been called the diathesis-stress theory (Rosenthal 1963). In its application to mental illness this view suggests that the susceptibility to mental illness, insofar as it is genetically based, varies along a continuum ranging from high to low extremes, most people clustering about an average of moderate susceptibility. Environmental stresses, also, vary from severe to slight. Accordingly, when a mental breakdown occurs, a combination of both factors is involved; thus, we should expect a high rate of breakdown among normal individuals subjected to severe stress, and a high rate also among very susceptible people placed under even mild stress. Such a quantitative relationship has been shown to hold in fact, e.g., in the neurotic illnesses of combat troops (Symonds 1943). Whether psychotic illnesses follow the same general law is a matter more difficult to decide.

Personality deviations and neurotic illness

Twin studies. An important part of the work in the field of personality deviations and neurotic illness has been studies of twins. One-egg, or monozygotic (MZ), twins, whose entire genetic equipment is identical, are of the same sex and are very much alike in physical characteristics. Two-egg, or dizygotic (DZ), twins ordinarily resemble each other no more than any pair of brothers or sisters and are as likely to be of opposite sexes as of the same sex. As a rule only the same-sexed DZ twin pairs are taken by investigators for comparison with MZ pairs. Twin pairs are said to be concordant when it is found that the twin of a proband (index case) with a particular deviation also shows the same anomaly. Concordance rates are usually given as percentages. Genetic hypotheses lead one to suppose that concordance rates should be much higher in MZ than in DZ pairs and that variability within MZ pairs should be smaller than within DZ pairs. Table 1 lists the percentage of concordances found for a variety of conditions, in which the statistics are based on at least thirty pairs.

Criminality and delinquency. Much effort has been put into the investigation of criminality and behavior disorder. The results of Rosanoff in juvenile delinquency are noteworthy (Rosanoff et al. 1934; 1941). There are high rates of concordance both in MZ and in DZ twin pairs, and little difference between them. This suggests that the similarity in the twins' behavior is due to common factors in their environment. It is at least possible that each of the twins constitutes part of the stress factor for his twin partner. The same suggestion arises from the observations of behavior disorder and neurotic traits in school children. Shields found that in these children the degree of neurotic reaction was more noticeably related to environmental factors than genetic constitution; the hereditary

factor showed itself in the type of reaction (1954). [See CRIMINOLOGY; DELINQUENCY; PSYCHOPATHIC PERSONALITY.]

Adult neuroses. Concordance rates are lower in neurotic adults, both in the MZ and in the DZ pairs. The greatly increased variability within both kinds of pairs can be put down to the much wider range of experience, and wider variety of stresses, to which adults are subjected.

Male homosexuality. At the opposite extreme are Kallmann's findings of 100 per cent concordance in MZ pairs, as against 12 per cent concordance in DZ pairs, for male homosexuality. This would suggest that in these cases the genetic factors account for the greater part of the variance. Some caution in interpretation is needed, however. The importance that the genetic contribution acquires here may be due to the fact that there was a predominance of the more constitutional type of homosexual in the sample studied by Kallmann and his team. [See SEXUAL BEHAVIOR, articles on SEXUAL DEVIATION and HOMOSEXUALITY.]

Studies of relatives. Attempts to estimate the importance of hereditary factors in causing neurotic illness have been made by investigating the frequency of such illnesses among the relatives of neurotic patients. Findings have varied greatly from observer to observer. One of the early workers, Brown (1942), started by investigating the first-degree relatives of patients who had been diagnosed as suffering from obsessional neurosis, anxiety neurosis, and hysteria, as well as those of a control group. Among the relatives of all groups he found individuals suffering from obsessional neurosis, anxiety neurosis, and hysteria, as well as from other personality deviations of a kind not easily named and classified. There were three significant findings: the relatives of the control group had much less psychiatric abnormality than the relatives of any of the other three groups; all three diagnoses were represented among the relatives of

Table 1 — Concordance rates for personality deviation and behavior disorders in monozygotic and same-sexed dizygotic twins

Deviation	Number of pairs	Investigator(s)	PER CENT OF CONCORDANCE	
			MZ	DZ
Male homosexuality	63	Kallmann 1952	100	12
Adult crime	216	Lange 1929; Rosanoff et al. 1934; Kranz 1936; Stumpff 1936; Borgstrom 1939	68	35
Juvenile delinquency	67	Rosanoff et al. 1934; 1941	85	75
Childhood behavior disorder	107	Rosanoff et al. 1934, 1941	87	43
Behavior disorder or marked neurotic traits in school children	41	Shields 1954	74	50
Neurosis, psychopathic personality	37	Slater 1953	25	14
Alcoholic addiction	82	Kaij 1960	65	30

Source: Shields & Slater 1960, p. 327, table 8.6.

all three patient groups; among those relatives who were classifiable under the three named diagnoses, it was found that there was a tendency for them to be in the same diagnostic category as the related patient. For example, of the nine obsessional relatives discovered, seven were related to the obsessional patients. This finding suggests a certain degree of specificity, which is best seen in the investigations which have been made on the relatives of obsessional patients (Luxemburger 1930; Lewis 1936; Rüdén 1953). Among the 100 parents of 50 obsessional patients Lewis found that 37 showed pronounced obsessional traits in one form or another; 21 per cent of the 206 siblings also showed obsessional traits. [See OBSESSIVE-COMPULSIVE DISORDERS.]

At the opposite pole are the findings in the relatives of patients diagnosed as suffering from "hysteria." The best family study was made by Ljungberg (1957), who found that among the fathers, brothers, and sons of hysterics, 2 per cent, 3 per cent, and 5 per cent respectively were themselves hysterics; and among the mothers, sisters, and daughters, 7 per cent, 6 per cent, and 7 per cent respectively. His observations also suggested that hysterical symptoms were not necessarily associated with hysterical personalities, and of the 363 hysterics whose personality structures were analyzed, 55 per cent were found to be nondeviant.

Similar conclusions were reached by the writer (Slater 1961) from a study of 24 pairs of twins, 12 MZ and 12 DZ, in which the proband had been diagnosed as suffering from hysteria. In none of these pairs was there a co-twin who had ever been diagnosed as suffering from hysteria, though abnormalities of personality and psychiatric illness were common. Among the relatives of these pairs the incidence of hysteria was even lower than in Ljungberg's material, and the anomalies found to be most noticeably in excess were manic-depressive and endogenous affective psychoses. [See HYSTERIA.]

It seems probable that environmental factors are more important than genetic ones in determining whether or not a man breaks down with a neurotic illness. But it would seem that genetic factors influence the predisposition to such breakdown, help to determine whether the personality is a stable one, and, in the event of breakdown, have a large effect on the type of symptoms which are likely to be shown.

Manic-depressive illness

The risk of affective psychoses in the first-degree relatives of manic-depressive patients is shown in

Table 2 — Per cent of manic-depressive disorders among relatives of manic-depressive patients

Investigator	NUMBER OF PROBANDS	NATURE OF RELATIONSHIP		
		Parents	Siblings	Children
Banise 1929	80	10.8	18.1	
Röll and Entres 1936	83	13.0		10.7
Slater 1938	138	15.5		15.2
Strömberg 1938	77	7.5	10.7	
Sjögren 1948	45	7.0	3.6	
Kallmann 1950	75	23.4	23.0	
Stenstedt 1952	216	7.4	12.3	9.4
Fonseca 1959	60	22.8	18.9	21.7

Table 2. It will be seen that there is much variation in the data reported by different observers. Nevertheless, these risk figures are all very much higher than would be expected of a sample taken from the general population, in which the incidence level is probably of the order of 0.4 per cent.

Approximately 15 per cent of the first-degree relatives of manic-depressives may themselves have affective disorders of the same generic group.

Single-gene explanation. One explanation suggests that there is a single dominant autosomal gene which predisposes a spontaneous variation in mood. Most people with such a tendency are likely to remain healthy throughout their lives, though their cyclothymic temperament may be clearly recognizable both to themselves and to their families. If such cyclothymic individuals are subjected to stresses, the spontaneous swing of mood into depression or elation may go so far and last so long that medical treatment becomes necessary; and then the patient may be stigmatized as a "manic-depressive." The genetic hypothesis proposes, in fact, to account for only a part of the causation. Environmental factors and threshold effects must also be playing a part. The theory requires that 50 per cent of the first-degree relatives of manic-depressives should be gene carriers; if only 15 per cent of the relatives show themselves as such, this can be put down to low penetrance of the gene. [See DEPRESSIVE DISORDERS.]

Polygenic explanation. A single-gene hypothesis, however, is not the only possibility; polygenic inheritance is an alternative explanation. Edwards (1960; 1963) has drawn attention to the fact that, in the case of common conditions, it is not easy to distinguish between the expected consequences of a single gene with diminished penetrance and of multifactorial inheritance with a threshold effect. Assuming that the predisposition to a condition, such as schizophrenia or diabetes, is quantitatively graded, with a normal distribution, Edwards suggests that when p = the frequency of the disorder, the incidence of the disorder in the first-

degree relatives of persons suffering from the disorder will be approximately \sqrt{p} . If the frequency of manic-depressive illness in the general population is approximately 0.004, then the frequency of manic-depressive illness in the first-degree relatives of manic-depressives should be about 6 per cent to 7 per cent. The observations are about double that figure, but it is not possible to say that observation and expectation, on the multifactorial hypothesis, are irreconcilable.

Schizophrenia

Extensive investigations of the hereditary factor in schizophrenia have been made by Kallmann and his associates in the New York State Psychiatric Institute and Hospital (Columbia University). A synopsis of the results obtained is given in Table 3. These risk figures should be compared with the estimated risk of schizophrenia for a member of the general population of 0.9 per cent. Environmental effects show up: association with a schizophrenic proband in the same home virtually doubles the risk of schizophrenia for step-sibs and spouses; and there is a greater risk for the non-separated MZ co-twin of a schizophrenic than for an MZ co-twin who has lived apart from the proband for five years or more. However, the table also shows the risk of schizophrenia running up steeply with increasingly close degrees of blood relationship. In view of these figures it is difficult and, the writer feels, unrealistic to dispute the conclusion that genetic factors play a significant role in the causation of schizophrenia.

The risk figures published by Kallmann are somewhat higher than those obtained by other workers but are in the main reconcilable with them. The writer, for instance (Slater 1953), found a risk of

76 per cent for the MZ co-twin and 14 per cent for the DZ co-twin, in a sample of 41 MZ and 115 DZ pairs. However, it is noteworthy that Essen-Möller (1941) in Sweden found larger differences within MZ pairs than were found by other workers, and investigations in Norway and Finland show tendencies in the same direction. Thus Kringlen (1966) collected 50 MZ and 94 same-sexed pairs, with concordance rates of 38 per cent and 14 per cent; and Tienari (1963) found that none of the 16 male MZ pairs he studied were concordant. It is possible that what is diagnosed as schizophrenia in Scandinavia is not quite the same as schizophrenia in Germany, Britain, the United States, and Japan. That there may be peculiar features about the gene distributions in northern lands is also suggested by the work of Böök (1953). In a remote part of Sweden north of the Arctic circle, in a population of farmers and lumbermen, he found a high incidence of schizophrenia, in a predominantly catatonic form; the incidence of schizophrenia in the relatives of probands, however, was also high, suggesting an intermediate gene with 20 per cent penetrance in the heterozygote. The possible prevalence of different genetic predisposing factors for schizophrenia in different parts of the world is a possibility which deserves investigation.

The findings of Tienari, by themselves, are anomalous and should not be taken as throwing doubt on the results obtained by others; they should be considered in relation to those of other observers, summarized in Table 4. In this table the figures relating to schizophrenia are derived from work in Germany, the United States, Sweden, and England. To these should be added the results obtained by the Japanese workers Kurihara (1959) and Inouye (1961). Inouye found concordance for schizophrenia in 60 per cent of 55 MZ pairs and in 12 per cent (two pairs) of the DZ pairs. Kurihara also found that 29 of 45 MZ pairs were concordant for schizophrenic symptomatology, but none of the 9 DZ pairs were.

The twin work on schizophrenia has been analyzed and discussed critically by Rosenthal in a number of papers (1962a; 1962b; 1963). He concludes that concordance rates have been artificially inflated by the sampling methods employed. Cases have been largely taken from standing populations and include an unrepresentative proportion of severe cases; if genetic factors are connected with reduced chances of remission (which has yet to be shown), this sampling would obviously bias the results. Clearly, sampling from consecutive admissions, or better still from birth registers, would be an improvement. Rosenthal criticizes standards

Table 3 — Per cent of risk of schizophrenia among relatives of schizophrenics

Nature of relationship	Per cent risk
Not related by blood, step-sibs	1.8
Not related by blood, spouses	2.1
First cousins	2.6
Nephews and nieces	3.9
Grandchildren	4.3
Half-sibs	7.1
Parents	9.2
Full-sibs	14.2
Dizygotic co-twins	14.5
DZ co-twins of same sex	17.6
Children with one schizophrenic parent	16.4
Children with two schizophrenic parents	68.1
Monozygotic co-twins	86.2
MZ co-twins living apart for at least 5 years	77.6
MZ co-twins not so separated	91.5

of diagnosis, both of zygosity and clinical classification, and considers that these diagnoses should be made independently of one another by different observers. Not all recorded work is equally open to such criticism; it is, for instance, a considerable safeguard to publish protocols in full, as the writer did, to make them available to rediagnosis by the reader. [See SCHIZOPHRENIA.]

Etiological theories. Rosenthal classifies the etiological theories of schizophrenia into (1) monogenic-biochemical, (2) diathesis-stress, and (3) life-experience theories, his own views inclining to a theory of the second type. This is no place for the discussion of the difficult problems involved, but the writer inclines to a theory of the first type. It can be shown (Slater 1958) that a monogenic theory fits fairly well with the empirically obtained figures for the frequency of schizophrenia in the siblings of schizophrenics, in the children of one schizophrenic parent, and in the children of parents both of whom had schizophrenic illnesses. These data can be reconciled with a gene of intermediate type, manifesting itself in all homozygotes but in only 26 per cent of heterozygotes; all but 3 per cent of schizophrenics would be heterozygous for the gene. This hypothesis clearly involves a massive environmental contribution in the causation of manifest illness and therefore differs from theories of type (2) only in supposing that the element of specificity in determining the type of psychosis is provided by the genetic constitution. One may expect that decisive support or refutation of type (1) theories will depend on biochemical investigations.

Presenile and senile dementias

Inheritance in Huntington's chorea is dependent on an autosomal dominant gene. Its incidence in the sexes is about equal. The age of onset, according

to Panse (1942), extends from early childhood to the late sixties, with a mean at age 36; Wendt and his colleagues estimate the mean age of onset at 44 (1960). These estimates mean that most of the children of gene carriers are born before the parent has developed the disease. Elimination of the pathogenic gene by processes of natural selection is, accordingly, very slow. The disease is slowly progressive and fatal, with a mean duration of 13 years (Wendt et al. 1960).

Unusual forms of presenile dementia are Pick's disease and Alzheimer's disease; both have a genetic basis. Compared with Huntington's chorea, they occur later in life, with a mean age of onset of 55, and with about seven years as the mean duration. Although the conditions are distinct pathologically, they are often difficult to distinguish clinically. According to Sjögren (Sjögren et al. 1952), the genetic factor in Pick's disease is most probably a dominant major gene, its manifestation subject to modifying genes; in Alzheimer's disease Sjögren thinks multifactorial inheritance more probable.

The problem of genetic determination in senile dementia is even more difficult. The most generally accepted opinion in the past has been that senile dementia is but one aspect of senescence and that specific genetic causation is improbable. However, this established viewpoint has been challenged by the work of Larsson, Sjögren, and Jacobson (1963). In a large study in Stockholm they found that senile dementia was not correlated with senescence. The relatives of patients suffering from senile dementia were not more than normally subject to other conditions, although their risk of senile dementia itself was increased; no instances of Pick's or Alzheimer's disease were found among them. There did not appear to be special factors for longevity whose presence or absence was connected with senile dementia. No evidence could be found of environmental factors of a sociomedical kind playing a part in determining the onset of senile dementia. Furthermore, there was no secular change in the incidence of the disease. Particularly in favor of an explanation in terms of a single gene rather than multifactorial inheritance were the variations in geographical distribution and the absence of intermediate states between senile dementia and normal aging in the siblings and children of the probands. [See AGING.]

The morbidity risk for senile dementia was found to be greatly increased among the relatives of the patients. These researchers consider that the best working hypothesis for the explanation of their findings is that of an autosomal major domi-

nant gene. This gene would be subject to diminished penetrance, the manifestation rate increasing with age. Only a minority even of the gene carriers would ever develop senile dementia; and since the calculated gene frequency was 0.12, the great bulk of the population would be immune.

II

ORGANIC ASPECTS

Traditionally, description of the organic syndromes, in relation to their effect upon the central nervous system and behavior generally, has included such generalizing conditions as cerebral arteriosclerosis, acute and chronic alcoholism, presenile and senile conditions, degenerative neural diseases, and developmental mental deficiencies, as well as conditions producing more focal disorders such as head injuries, brain tumor extirpations, and cerebrovascular accidents (the boxer who is punch-drunk or the stroke patient).

The trend in recent literature, however, confirms what is a notably progressive shift in emphasis away from strictly clinical or case description, as exemplified by texts in psychiatry and neurology, toward more varied studies, which consider psychodiagnostic and psycholinguistic phenomena in the context of clinical observations.

With these important changes in the study of organic pathology has also come a voluminous growth in the literature. Within this literature (see Wepman 1961) can be found the continuing traditional interest of the neurologist and psychiatrist, as seen, for example, in the recently published *American Handbook of Psychiatry* (Arieti 1959). However, the great breadth of the field can be noted in the work of experimental psychologists using both animal and human subjects; in the recent neurophysiologic research on such central nervous system areas as the reticular formation, the limbic lobes, and the association tracts; in the dramatic electrode stimulation studies of cortical reactions carried on during neurosurgery; in the elaboration of new psychodiagnostic signs by psychometric researchers; and in the growing group of neurophysiological theories related to brain func-

tion. Additional examples, from the more applied fields, are rehabilitation for brain-impaired persons and the not inconsiderable addition of research on language disabilities.

As can be seen, the literature of neuropsychology is rich and varied. Within it, the reader will find, however, that there are more unknowns than knowns, more questions than answers, more theories than facts. While a great deal has been written about the behavior of the brain-impaired, very few facts have been demonstrated. For example, it is generally accepted that in thought, emotional control, and intellection, the role of the central nervous system is crucial. Yet the precise manner in which the nervous system and the human brain work to fulfill this function is undetermined and vague. A leading neurophysiologist once described the human brain as a "black box" that must function in certain well-prescribed ways in order to produce all that it does in human behavior but unfortunately is not available for viewing.

Nevertheless, the great concentration of attention by so many trained observers, the extensive studies of clinical cases, the host of theories, the wide and growing application of differential diagnostic techniques, and the increasing activities of both language therapists and psychotherapists treating patients suffering from brain impairment have all produced a considerable body of knowledge available for better understanding of organic mental disorders. The following is an attempt to describe some of the more prominent behavioral phenomena commonly associated with neural impairment and includes major sources of data and references in order to facilitate and encourage further investigation by the reader.

Common behavioral manifestations

Alteration in thought, personality changes, and changes in language comprehension and usage take on many forms following cortical insult. By and large, however, most investigators agree that individual patterns of behavior in the brain-impaired differ from those of the unimpaired more in degree than in type. Table 1 presents the reader with a list of the most common indications of brain impairment.

While space limitations preclude extensive comment on the relative merit of individual signs of organicity as indicators of organic psychopathology, some generalizations about them are warranted. Many of these signs appear as the result of a dis-ordering process producing abnormal behavior; others are the product of the retained ability to function of what is left of the nervous system; and

Table 1 — Behavioral symptoms of the brain-impaired

CLINICALLY OBSERVED SYMPTOMS	PSYCHODIAGNOSTICALLY ELICITED SYMPTOMS	LANGUAGE DISTURBANCES
Memory loss especially immediate memory.	Poor attention and concentration	Aphasia
Reduced association of ideas	Memory loss	Agnosia
Perseveration of thought and language	Abstract-concrete imbalance	Aprosodia
Feelings of inadequacy	Poor ability to organize and preplan	Dysarthria
Egocentricity	Difficulty in forming generalizations	
Hyperirritability	Inability to categorize	
Overfatigability	Lowered general intelligence	
Euphoria	Psychomotor retardation	
Catastrophic overreaction	Perplexity (questioning one's own ability)	
Reduced initiative	Psychological impotence (recognition of errors without the ability to alter responses)	
Lack of spontaneity	Egocentricity	
Impulsive behavior	Anxiety	
Regressive behavior	Specific modality disabilities in learning	
Fluctuating ability	Body-image distortion	
Situational or fixed anxiety	Spiral afterimage reactions	
	Delayed response patterns	

still others derive from the altered self-concept of the people involved (their reactions to their impairment). At any rate, these signs, while not necessarily pathognomonic of the brain-injured, are rather useful indicators of the likelihood that a cortical impairment has occurred. Research comparing known brain-impaired subjects with normal individuals and subjects with thought disorders (for example, schizophrenics) has consistently shown that pathological conditions, while frequently unlike normal states, are most often like each other (Chapman 1960). In fact, the argument has been advanced that the very presence of so many so-called organic signs in schizophrenia may indicate that this psychiatric condition is indeed an organic psychosis. Thus, behavioral symptoms can be viewed as frequently occurring telltale indicators of pathology but cannot themselves be viewed as differentially diagnostic signs of organic pathology.

It should also be pointed out that most of the signs used as organic indicators have not been found by research studies to occur in every organic condition. In part this is true, the present writer feels, because few of the studies have been really comparable. Research populations differ in so many ways (for example, age of subjects and location and extent of lesion or impairment) that the signs said to be associated with brain pathology in one study may be completely lacking in an equally well attested study of another group of brain-injured patients. A final source of inconsistency is related to subjects with a known brain injury but who differ in behavior from other such subjects even though neuropathies may be alike, the location of damage is thought to be the same, and the amount or size of the lesion is thought to be

roughly equal. The generalization must be made, therefore, that brain-impaired patients differ from one another not only in the size and location of their structural defect but also in the behavioral aftereffects of similar neurological impairment.

Certain commonalities do exist, however, and it is to these that students of brain pathology turn in attempting to gain a greater understanding of cerebral function and dysfunction. The remainder of this article will be concerned with a more particular discussion of the behavioral signs appearing in Table 1 in relation to organic disorder, with emphasis upon the literature and major sources of data. Shortage of space unfortunately limits consideration to only the most prominent and generally elicited signs appearing in each of the three categories arbitrarily designated as clinically observed behavior, psychodiagnostically elicited behavior, and psycholinguistic disturbance patterns.

Clinically observed behavior. Many of the signs enumerated in the category of clinically observed behavior can be related to certain basic processes that seem to underlie the signs themselves.

Lack of control over behavior. Most important among these processes is the concept of "control." Since the central nervous system is generally considered a major determinant in the control of behavior as the individual seeks to adapt to his environment, loss of memory and similar behavior may be best understood in this context. As a loss of selective control over recall of events in the past. Further, memory loss in organic conditions is said to be most severe in the area of recall of very recent events, for example, when the individual must select (control) the appropriate associations from a variety of recent ones. Related to the

recall aspect of memory loss is the loss of capacity to attend, concentrate, or exert simple control over one's ideas.

Impulsiveness, emotionality, and rigidity. Similarly, many clinicians have observed that the brain-impaired child is impulsive and emotionally labile. They react catastrophically to noncatastrophic events, or they become easily frustrated. At the other extreme, the brain-impaired often display tendencies toward rigidity or repetition in thought and language, find it difficult to shift from one idea to another, and are frequently inflexible in behavior. In each case then, these signs point to the patient's inability to regulate his behavior in a flexible fashion. Lack of adequate inhibition and sufficient control brings about these overt behavioral patterns, which have been termed symptoms of brain damage. With adequate control the unimpaired behave with intent, behave appropriately, and behave purposefully. The impaired, having lost control, show abnormalities of behavior in all three areas. (Note: The writer feels it is unnecessary to discuss clinically observed symptoms more extensively here, as they are generally self-explanatory; however, more detailed consideration may be found in the references cited in the bibliography.)

Psychodiagnostically elicited symptoms. The loss of perceptual ability is a basic process that frequently affects the brain-impaired. This loss of function is especially noticeable in the capacity to learn through specific sense modalities. Consequently, it is most often described in relation to deficiencies of children with known neurological deficiencies. But it seems equally true in all adults with brain damage, where perceptual deficiencies have been noted as being modality-bound rather than generalized. Auditory perception, for example, may be affected by brain impairment or by failure of certain portions of the nervous system to develop, while other perceptual abilities may remain intact (Wechsler, 1958). Some children, it has been noted, fail to develop language at the time expected of them, that is, by two or three years of age. This is not because of any lack of general intelligence or because of deafness or emotional instability but rather because they are unable to learn in situations that involve the auditory pathway. Other children, who do speak adequately, have been observed having difficulty in learning to read at the expected age. Again this may be caused by, or rather result from, their inability to use the visual modality in learning, and thus despite the noticeable adequacy of their verbal ability. See HEARING, VISION.

These auditory and visual agnosias in children are paralleled by similar disturbances of transmission of input stimuli following cortical insult in adults. Perceptual learning disability along specific modality lines has become the center of attention for many students of behavior in brain-impaired children and adults.

As Table 1 implies, many signs of organic brain impairment can be elicited by psychometric and projective assessment. In some instances these are found to duplicate the clinically observed signs. But in others they are observed only when the subject is under the stress and scrutiny of formal testing.

Verbal and nonverbal functioning. The use of psychological tests as a means of isolating behavioral indicators of brain impairment continues to be a source of considerable research. Babcock (1941) noted in her studies of the brain-injured that certain intellectual functions seem better retained after trauma than others. She then proposed to study subjects and evaluate their product in terms of these better retained areas (verbal behavior) as compared with the abilities that are less well retained (visually stimulated abstraction ability). A similar differentiation was used in the Shipley-Hartford Scale (Shipley, 1941) and the Hand-Minnesota Test for Brain Impairment (Hand, 1943). Some support for this system has seemed to follow from the characteristics of the tests used. Vocabulary tests, or verbal ability as measured by most tests, is active, it is well repeated with general intelligences, is known to have a high test-retest reliability, and is generally a stable measure. In contrast, the tasks of visual abstraction are less stable, have less reliability over time, and are therefore likely likely to be susceptible to change as a result of organic conditions affecting the nervous system.

Wechsler followed the concept of retained as opposed to sensitive functions and in a comparison of verbal versus nonverbal behavior had in effect a very determined response to various contexts to his intelligence scale. From the results of his studies of an aging population he derived a *Verbal-Nonverbal Index* (VNI) (1954, p. 46). This approach has taken into account several pathologies known over some preliminary research in the literature fostered by the organic matter has been lacking (Koss, 1943). Those who argue against the use of the verbal versus the nonverbal difference, or, as the believers in perceptual learning put it, "the difference between active and visually stimulated behavior" having and visually stimulated behavior.

seem to this writer to be correct in their conclusion—but for the wrong reasons. In none of the research reported on the many indexes of deterioration was any attempt made to isolate the location of the organic condition, even to the rather loose degree of determining the hemisphere affected. Yet many language studies (Wepman 1951; Ettlinger et al. 1956) and the work of such researchers as Reitan and Reed (1962), Milner (1954), Bauer and Wepman (1955), and others have reported each of the two hemispheres differentially responsible for various intellectual tasks. [See INTELLIGENCE AND INTELLIGENCE TESTING.]

In conclusion, therefore, it would be expected that the verbal-nonverbal paradigm would be successful. When damage has occurred to the left brain (the apparent site of integrations necessary for verbal behavior) it would seem that subjects should do less well with verbal than with nonverbal material. When, on the other hand, notable damage occurs in the right hemisphere, which, according to many studies, is the locus of control and integration for nonverbal thought, the expectancy would then be that nonverbal material would present greater difficulty. To the degree that such a distinction can be made in psychological tests—and it can be in many of them—the tendency for the effects of brain damage to be depicted seems high. Re-examining known organically impaired subjects from this viewpoint shows this differentiation to be a meaningful one. The degree to which this approach can be used in differential diagnosis where brain damage is suspected but not certain, however, still needs research verification.

The qualitative approach for the delineation of personality disorganization, using projective tests as the source of data, has proven of value in the hands of many psychologists (Aita et al. 1947; Baker 1956; Hughes 1948; Piotrowski 1937). Unfortunately, most of the results reported are the subjective interpretations of individual examiners and are barely or not at all confirmed in replicated studies. Where such studies have been attempted, few of the signs found diagnostic by one examiner have been elicited by others. For the purposes of demonstrating some of the psychodynamic processes affected in many brain-injured subjects, however, the different projective techniques have proven of considerable value. Yet even here it seems important to point out the individual variability in behavioral reactions. Since brain-injured subjects differ so markedly, for example, in their responses to their traumas, or with respect to their self-conceptions, it has been found to be of little value

to look for commonality of reaction in personality change.

Abstract and concrete functioning. Goldstein, perhaps more than any other student of brain disorders, has postulated both specific disabilities and changes in basic attitudes and thought processes as a result of organic conditions. He pointed out that "... even in cases of circumscribed cortical damage, the disturbances are scarcely ever confined to a single field of performance. In such intricate syndromes, we deal not only with a simple combination of disparate disturbances but also with more or less unitary, basic change that affects different fields homologously and expresses itself through different symptoms . . ." ([1934] 1939, pp. 15-16).

Of all the symptomatology noted in the study of the organic psychopathologies, none has had greater impact or perhaps stirred greater controversy than Goldstein's concept of the shift from the abstractive to the concrete mode of thought (Goldstein & Scheerer 1941). With his co-workers, he postulated both theory and methods for determining the loss of categorical, abstracting behavior. The concept, by and large, has received greater acceptance than the methods. Today almost every clinician studying the behavior of the brain-impaired patient concedes the correctness of Goldstein's observation that organic brain disease impairs abstract functioning. The many Goldstein tests, however, have been less successfully used by other examiners.

Changes in intellectual performance. Finally, some attention should be directed toward the concept of changes in general intellectual level as a consequence of brain impairment. Essentially, there are two types of change that have been widely noted. In some patients, over-all intellectual level seems grossly affected, as in conditions that to a certain degree affect the nervous system in its entirety. A good example is the deterioration that accompanies progressive cerebral disease and that is demonstrated by progressive generalized intellectual decline. In other patients, the condition is localized and affects intellectual ability within fairly circumscribed areas. It can be shown in most cases of brain disorder that one or the other of these two forms of intellectual loss occurs. In certain types of localized damage that affect only specific functions, as in the limited agnosias and apraxias affecting language, it may be held that no intellectual loss need be predicated. However, even here a loss must be considered to occur, since the deficiency in those functions immediately affected makes adaptation to the environment more difficult and more circumscribed. Thus, even very minor

brain damage that functionally affects only the capacity to read or write and that might not affect the individual's capacity to think or perform on intelligence tests would still have its deleterious effect upon the totality of behavior and, consequently, upon intelligence. It would make the patient a less efficient organism and would thus make adaptation to life a more complex task for him.

Generalized deterioration, whether progressive or not, rarely permits alterations in behavior through therapy and rehabilitation. On the other hand, focalized injuries that produce limitations of intellectual ability can frequently be offset by proper training and therapeutic rehabilitation (Harlow 1953).

Organic language disturbances. Language function and dysfunction have also become the focus of attention of many researchers in recent years. Loss of the ability to comprehend and use language has an extensive literature of its own. Aphasia, a loss of ability to utilize verbal symbols, is a relatively common aftereffect of brain damage, especially when that damage affects the left cortical hemisphere. There have been widely different approaches to the study of the language syndromes. Schuell and Jenkins (1959) have postulated that language is a unitary process that may be lost in varying degrees. They have concluded from their studies that the language deficit may be measured along a continuum of severity of dysfunction. This would include difficulties with a variety of individual tasks, such as the abilities to speak, read, and write. Wepman and Jones (1961), on the other hand, contend that language is divisible into a series of different linguistic processes and that each process may be differentially affected. Five types of symbolic loss of language—five types of aphasia—have been described in this research: global, jargon, pragmatic, semantic, and syntactic.

Partial support for this viewpoint is seen in the insightful work of Jakobson (Jakobson & Halle 1956), who related certain observed aphasic disturbances, noted above as semantic and syntactic aphasia, to two basic linguistic processes. He pointed out that there are two basic types of aphasia, differentiated according to whether the deficiency is in the selection and substitution of words or in their combination and contexture.

Further support for this linguistic differentiation also comes from other sources. The research of Goodglass and his co-workers on agrammatism and paragrammatism (Goodglass & Hunt 1958; Goodglass & Mayer 1958) confirmed the Jakobson dis-

tinction. The work of Lurii (1947; 1958) in the Soviet Union goes far beyond the linguistic approach, identifying the process changes with neural constructs and specific localization of damage. Also included in his work is a description of five very similar types of language disturbance (1958).

The conception of aphasia as representing disorders along a continuum of severity and the psycholinguistic classification of aphasic types as discussed above are fairly recent developments. In contrast, traditional neurological literature treats language disturbances as receptive or expressive disorders, closely related to specific neurological substrata. Indeed, a fair proportion of the literature on the whole field of brain damage is given over to discussions of the question of localization of function in the nervous system. Harlow's review of literature dealing with the higher functions of the nervous system (1953) is devoted solely to the difference of opinion concerning localization. Discussing Hebb's brilliant *Organization of Behavior* (1949), the Hixon Symposium on *Cerebral Mechanisms in Behavior* (Jeffress 1951), and Fulton's *Functional Localization in Relation to Frontal Lobotomy* (1949), as well as research devoted to specific architectonic divisions of the cortex, Harlow concludes in part that "the data would appear to be almost overwhelmingly opposed to any theory of cortical localization of intellectual function which is anatomically precise or temporarily static" (1953, p. 512). Writers in the field vary from a position of extreme belief in punctate localization to the opposite view of equipotentiality or mass action. Somewhere between these two polar viewpoints rest the opinions of most present-day exponents of the role of the cortex in relation to behavior.

Recent reports of psychodiagnosticians studying the behavior of patients with known brain damage give some credence to a gross type of localization. Reitan and his co-workers (Reitan & Reed 1962), as mentioned earlier, have been able to show that subjects with left brain damage, when tested by such scaled instruments as the Wechsler Adult Intelligence Scale, show a greater deficit in performing verbal tasks, and less deficit, if any, in performing nonverbal tasks. The opposite findings were reported on patients with known right brain damage; that is, they did better on verbal tasks than on nonverbal ones. This general finding bears out what has previously been said about language disorders following brain injury; that is, symbolic verbal behavior is found to be disturbed only in left brain-injured subjects (Wepman 1951).

It is the viewpoint of most students of brain function that while there is a type of localization of function within the nervous system, the end product, which is an individual's behavior, is the result not of the functioning of any localized section or subsection but of the integrated nervous system as a whole. For example, Penfield and Rasmussen (1950), by their ingenious placement of electrodes during neurosurgery, have demonstrated that while aphasic arrest does occur more frequently when Broca's area (the third prefrontal convolution of the left cortex) is stimulated electrically, a similar arrest of language occurs when widely scattered areas of the parietal and even the temporal lobes are stimulated. From such studies it would appear that while a high concentration of cells in Broca's area may be responsible for a type of word-finding ability, other areas subserve the same function but in a less concentrated way. Behavior, it is held, is a far too complex process to be conceptualized as the product of any localized area of the brain. It is much more reasonably thought of as the integration of perceptual, conceptual, mnemonic, and motor processes—with factors of motivation, emotion, and the processes of feedback playing their various roles.

Organic mental disorders can thus be best described as the results of a variety of conditions—disease processes, traumas, agenesis, deteriorations, etc. These conditions in turn produce alterations in the consequent behavioral patterns of the brain-impaired. Certain specific signs of alteration are more commonly seen in the behavior of the impaired than in the unimpaired. These signs are recognizably not pathognomonic of the neural disorder. Yet, by their consistency of occurrence, they are often the best indicators available of brain damage in those in whom pathological behavior is noted. Many of these indications are admittedly seen only clinically and rarely verified by research. Others are elicited through more organized and scientific psychological and linguistic studies.

III BIOLOGICAL ASPECTS

In 1884 the founding father of neurochemistry, J. W. L. Thudichum, wrote:

Many forms of insanity are unquestionably the external manifestations of the effects upon the brain substance of poisons fermented within the body, [in the same way that] mental aberrations accompanying chronic alcoholic intoxication are the accumulated effects of a relatively simple poison fermented out of the body. These poisons we shall, I have no doubt, be able to isolate after we know the normal chemistry to its uttermost detail. And then will come in their turn the crowning discoveries to which all our efforts must ultimately be directed, namely, the discoveries of the antidotes to the poisons, and to the fermenting causes and processes which produce them. (1884, p. xiii)

Thudichum anticipated trends which we would regard as very modern in our day. Two premises are explicitly stated. An aberrant biological product (or "a product fermented in the body") leads to aberrant behavior; and knowledge of normal chemistry "to the uttermost detail" is an essential prerequisite to the isolation of such a product. Thudichum's own crowning achievement was an analysis of the brain in terms of its chemical building blocks, the so-called lipoproteins, which are complexes formed between fatty bodies (lipids) and proteins. This work still stands as a classic.

Yet this approach—what one might call a clockwork approach—reflects the hopes and limitations of an age. In the Victorian era, governed by the meter rule, the clock, and the kilogram, an under-

standing of the chemical machinery was regarded as a reasonable basis for the understanding of mental disorder and thus, by inference, of mental order. Attitudes have great viability; similar approaches (with somewhat better reason) are with us to this day. They aim at an understanding of the chemistry of the strange detector we carry in our skull. But of environment, forever playing upon this detector, and so often disrupting and distorting it, chemistry will tell us nothing. Nor can chemistry, in its old and classic form, tell us much of how environment is transcribed and coded by nervous tissue.

Yet in man the brain in some strange way internalizes and stores environment; it models it in sight and sound and uses these models as predictors; it transmits information from generation to generation by a symbolic (nongenetic) process, which is a radically new departure in evolution. Neurochemistry thus poses problems very different from those posed by classical chemistry or even by modern physical chemistry. It demands a revision of attitudes, and perhaps like no other field in biology is forcing a confrontation of biological process with the emerging concepts of system theory. In short, any attempt at understanding the brain as a chemically mediated organ of information forces an encounter between somatic transaction and symbolic process. This field one can, justifiably, term psychobiology.

Principles of regional brain organization

We may be a long way from understanding the nature of the chemical control processes which enable the brain to function as an integrating, "feeling," information-storing, predicting, and computing organ, but we have also come some way since Thudichum. Thudichum's analysis involved the analysis of the brain as a single organ. However, the brain, unlike the liver, is not a homogeneous organ; and in terms of anatomical arrangement, cell population, and chemistry it shows a regional economy which reflects the course of its own evolution. The distinctive attribute of the human and primate brain is the size and structure of its cortex. Its contribution to the analysis of secondary signaling (that is, symbolic) systems has been extensively studied by the Pavlovian school. Yet work since the 1940s has also emphasized the role of some developmentally older subcortical centers buried deep in the brain and the relationship of these structures to the cerebral cortex. The brain centers in question are the hypothalamus, the reticular activating system, the rhinencephalic ("smell brain") formation (also known as the limbic system), and the caudate

and lentiform masses (the corpus striatum). Each of these systems has received its share of extensive review; and accumulated experience, using a variety of techniques with each, has steadily emphasized three separate, though related, trends. The first is the discrete neuroanatomic and cellular suborganization of these systems; the second, the interconnectedness between the systems themselves and between the systems and relatively distant elements at high cortical and spinal levels; and the third, the reciprocal, complementary, yet mutually exclusive relationship which some patterns represented in these systems bear to each other. These findings are relevant when considered in relation to the regional chemistry of these structures. [See NERVOUS SYSTEM, article on STRUCTURE AND FUNCTION OF THE BRAIN.]

There is little doubt of the anatomical heterogeneity and cytological differentiation of the hypothalamus, where small areas measuring hardly more than a few millimeters in diameter control the central representation of the autonomic nervous system and the appetitive drive systems (fight, flight, hunger, thirst, sex). Similarly, more recent studies have emphasized the remarkable anatomical and cytoarchitectonic differentiation within the reticular activating system, governing wakefulness, sleep, and focused attention. Elements in the structure of the limbic system have similar differentiation. Each of these systems thus encompasses a mosaic of subsystems which in a manner only poorly understood at present are fitted into one another. This understanding, however, is being steadily enhanced by mounting knowledge of the anatomical connections and electrophysiological properties. These connections are in both directions between the hypothalamus and the reticular formation, the limbic system and the hypothalamus, and between these structures and the cortex. [See ATTENTION; SLEEP.]

The term "limbic system midbrain circuit" is entirely apt (Nauta 1958). In a way still poorly understood, the limbic system would appear to be an intermediate between discrete analysis of diverse signals at high levels and the discharge of a limited genetically coded stereotyped response known as "affective" behavior. It appears to participate in and to modulate both.

There is a tremendous convergence of information in this area. There are structural counterparts of this convergence; in the olfactory bulb, for example (which in man can be regarded as a homologue of the hippocampus), the messages of about 50 million receptors are reduced to 150 thousand in mitral cells and finally reach the brain through

the axons of a mere 45,000 pyramidal cells. These cells and their branchings thus have the structural features which make for an extraordinary funneling and filtering of information (Green 1964). It is, incidentally, in these areas too that a rich, tessellated, terrazzo-like apposition of shared membranes, a virtual mosaic, is found. These junctional areas are also highly localized electrical generators.

It is usually found convenient to speak of the reticular formation and the hippocampal amygdaloid cell assemblies as areas that control sleep, wakefulness, and the states between wakefulness and sleep. Yet there is evidence that these areas are pre-eminent in their relation to patterns of emotional expression of autonomic functioning and, also, that interference in these areas may be important for the process of "recall" and possibly for the process of registering the memory trace. Seen dimly, then, and in broadest silhouette, the functions covered by the terms "consciousness," "affect," and at any rate "recall" thus appear to be subserved by congruent or at least intimately connected systems (Elkes 1966). That we are "aware," that we are "responsive," that we are "appropriate," that we can *plan* a piece of behavior and be *sequent* rather than random, confused, and "in-consequent" in its execution may well be due to some elements and processes vested by evolution in these remarkable cell groups. Somehow, they appear to have the ability to build short-term representational systems of temporarily related events and to use them in the construction of appropriate responses. These models, these tiny maps in time, may be intercellular or cellular; at this stage we do not know.

We may thus regard the brain as a mosaic of what have appropriately been called "biased homeostats" (Pribram & Kruger 1954). The bias, handled by genetically coded "Yes-No" drive systems, keeps changing constantly in the light of ongoing events. To allow adequate comparison of events, slow-fading traces must be available to set up such transient comparisons. It is possible that the so-called after discharges (slow-fading electrical discharges) for which the cells—particularly of the hippocampus—are noteworthy provide a medium for the establishment of such traces. In a manner which is only just beginning to be understood, the coincident is detected and the concurrent arranged into an appropriate action that is *consequent*. Whereas internal perception and comparison may be multiple, action and preparation for action are essentially serial: it requires a rigorous regulation of construction of events at the time; it demands apprehension of the redundant and, above all, a selective inhibition of those elements which are

judged irrelevant; a construction of subsets which carry meaning by ignoring but also can carry coded traces of what they ignore. Inhibition is thus the agent of structure in the central nervous system. This is borne out by all that we know of reciprocal inhibition in the spinal cord and all that is being learned of the organization of sensory processes. All evidence coming from visual, auditory, and the somatosensory fields points to the operation of highly patterned inhibitory processes reciprocating with the excitation. Delay of the immediate response—that is, the reduction of the immediate reactivity—is merely the giant child of inhibition, a vast and pervasive function woven by evolution into the nervous tissue as a device for judging relevance and for structuring time. Time, indeed, would appear to be the main axis around which the nervous system constructs its model of reality. It does so by judging what is relevant in time and “banking” what is irrelevant. The higher nervous system is remarkable for its ability to ignore; accurate adaptive performance is attained by ignoring all that is adjudged irrelevant.

Somehow, then, in such transactions the simultaneous has to be changed to the successive, and global or random apprehension likewise has to be transformed into rank-ordered sequential responses. It has been observed by Pribram and Kruger (1954) that it may be the role of the limbic system to provide the context in which drive stimuli are reinforcing and then to reverse the context-content relationship between the drive stimuli and reinforcing events. Thus affective connotation becomes a label and a gating device. Affect gates the emergence of memory traces into preconscious knowing and conscious action. The events and the internal representation may be highly varied and complex; the affective response patterns, however, are finite. Seen very broadly, the anatomy of the neuraxes reflects these requirements. For we are dealing here with two great vertical systems and one, so to speak, horizontal system.

First, there is the so-called specific afferent-efferent system which in particular preserves information coming from receptors in a point-to-point representation; second, there is the core of the midline structures comprising the massive facilitatory and inhibitory structures and characterized by a great variety of cells which serve as a mixing pool for each sense modality. Connected with both systems are the elements of the limbic system in which the indications for somewhat longer traces of activity (the so-called “after discharges”) are located and which makes this information available for reference, for comparison, and for label-

ing. It is possible that the caudate and the striatal nuclei may have somewhat similar properties. In man the vast neocortical mantle provides a tremendous reservoir of cells for the storage of recorded traces of events and for their use in the shaping of new events, either symbolic or actual, i.e., those expressed in action. It is also well to recall that wherever we look in the central nervous system, extracellular space is scarce; nonneuronal (so-called) glial structures and membranes predominate. In fact (although this may prove to be an extravagant generalization), we may look upon the central nervous tissue as an array of growing, polymerizing protein fibers and a mosaic of lipid-protein membranes.

Studies have shown the power, the growth, and the specificity of connection formation in the peripheral nervous system. There is also evidence of the presence of nerve growth factors promoting the growth of nerve fibers (Levi-Montalcini & Angeletti 1961). It would seem that, scaled down and compressed to an enormously faster time scale, we may be dealing in the central nervous system with the growth and evolution of macromolecular forms, which by their interaction determine what we know as symbolic form. The junctional sites between cells, and particularly the enormous and highly ordered membranes existing in the central nervous system, may play a part in the initial construction of trace models capable of acting as recognizers, and hence as organizers and ultimately as decision points—organizers, that is, of coincidences, of sequences of pattern, that is, patterns in time. [See TIME, article on PSYCHOLOGICAL ASPECTS.]

Central neurohumoral substances

It may very well be asked why one should emphasize structural features in the context of a statement on the biological background of mental disorder. The partial answer is that the anatomical and functional attributes have some suggestive chemical correlates. For it is precisely in the areas just mentioned (the hypothalamus, the midline gray area, and elements of the limbic system, the amygdala, the hippocampus, the reticular activating system, and certain layers of the cortex) that one repeatedly encounters a number of small molecules which appear to have evolved for a role in the organization of control systems in the central nervous system. These molecules are acetylcholine, and possibly other choline esters; gamma aminobutyric acid, a derivative of glutamic acid; histamine, also found in the skin and released in injury of all tissues; catecholamines such as dopamine, norepinephrine, and epinephrine, mediators of

sympathetic system responses at peripheral effector sites; and indoles such as serotonin. All these molecules show a regional gradient in their distribution. Histamine, for example, is found principally in the midline diencephalic structures; norepinephrine is present in the hypothalamus and in the periventricular gray matter; serotonin is present in both diencephalic and limbic structures. Two further features should be emphasized concerning these substances. First, they are representative members of *families* of compounds. As chemical mapping proceeds, related members of these various subgroups, their precursors, and their products are identified. Second, the metabolic pathways of each of these compounds—within and without the brain—are steadily being defined more clearly. New and elegant techniques are capable of demonstrating these materials *in situ* in the brain. These studies show that the intercellular and pericellular economies of these substances are organized very precisely. The molecules are transported into cells or their precursors by the energy-yielding system; once synthesized, they are transported and packaged into granular particles or "vesicles" inside cells; they are carefully stored in equilibrium at these sites and are released in response to electrical stimulation by mechanisms still poorly understood. Moreover, all work so far on how the psychoactive drugs act—be they tranquilizers, stimulants, or the so-called hallucinogenic compounds—suggests that all substances interfere in varying ways and to varying degrees with the uptake, storage, and release of the catecholamines (such as epinephrine and dopamine), indolic substances (such as serotonin), and possibly histamine in the areas that have been mentioned. The precise action profiles of these drugs are different, and it is upon such subtle differences in action that variation in therapeutic effect may well depend.

This, then, puts an end to the simple "clock model" of an earlier day. For we are not only dealing with *families* of compounds, but we are also considering multiple binding sites of organelles exquisitely sensitive to local subcellular conditions. The uneven distribution of these chemicals at neuronal decision points, the trigger (or selective suppressor) function of certain elements, and the anatomically imposed economy in terms of convergence and occlusion all suggest that we are dealing with transaction sites at highly localized subcellular levels which need not necessarily be reflected in gross over-all shifts. These sites are evidently unevenly distributed in nonhomogeneous cell populations. Their state at any one time depends exquisitely upon the short-term history of preceding or

coincidental events. It is impossible to think in terms of a mechanistic spatial localization, i.e., in terms of points. Rather, one is forced to think in terms of convergence, coincidence, stochastic processes, and probabilities of interaction in time. It was earlier suggested that inhibition is the agent of structure in the nervous system and that the silence in the central nervous system is, so to speak, informed silence. The chemical computer we carry in our skulls apparently writes its chemical text of experience in proteins; and some small molecules appear to play a key part in the transcription or readout. Much work on the biology of mental disorder centers on the identification of the normal molecules mentioned above and of their deviant metabolites.

Chemical aspects of mental development

Chemical factors certainly operate in the development of the nervous system. Some of these are general; others are more special. Of the general factors, oxygen supply is one and hormones are another. Cerebral ischemia, i.e., restriction of blood supply, even for a short time in the developing animal, causes marked forms of mental deficiency. Yet in the adult animal, oxygen supply and fuel consumption are not necessarily related to mental functioning: they may be, but they need not be. A major advance in methodology (Kety & Schmidt 1948) has made it possible to make exact measurements of blood flow, oxygen consumption, and glucose consumption in the conscious human brain, in a variety of functional states in the normal brain and in various forms of mental disorder. These studies have shown quite clearly that in normal man the major substrate for oxidation is glucose and that the rate of energy utilization of the human brain is on the order of a mere 20 watts—eloquent testimony to the efficiency and miniaturization of the brain—computer, weighing about three pounds.

These same studies also showed that general anesthesia reduces cerebral oxygen consumption to about 40 per cent; in contrast, normal sleep did not show such reduced oxygen consumption. Similarly, in studies of schizophrenia and of the effects of LSD-25 and other hallucinogenic drugs there were no changes in over-all total oxygen consumption. First and last, the brain is an organ of information. To be sure, energy is needed to keep the living computer going, to synthesize the building blocks, particularly proteins and lipoproteins essential for its development. However, information storage and retrieval are evidently low-energy processes.

Another equally general factor concerned in intellectual development and mental functioning is presented by a number of hormones, of which thyroxin can serve as a useful example. Hypothyroidism due to an iodine deficiency leads to a mental deficiency syndrome known as cretinism. Hyperthyroidism (an excess of thyroxin) leads to striking hyperirritability and various signs of overactivity of the autonomic nervous system. There is much experimental evidence (Sokoloff & Kaufman 1959) that thyroxin may exert its action on the brain through influencing protein synthesis. It is relevant that although thyroxin does not stimulate protein synthesis in the mature brain, it does significantly do so in the newborn brain. The main structural defect in experimentally induced cretinism (produced by thyroid deficiency) is a deficiency in the proliferation of fine nerve *fibrils* (dendrites) in the immature cerebral cortex. Here again, a structural feature stresses the importance of *connectivity* between neurones (the so-called *neuropile*) rather than mere *number* of cells.

The pathology of phenylpyruvic oligophrenia (phenylketonuria, PKU) may serve as a useful example of the way in which a specific and genetically determined metabolic error—a so-called biochemical lesion—may profoundly affect the development of higher nervous function. In 1934 A. Z. Folling observed in the course of an investigation of mentally defective children that some of them excreted phenylpyruvic acid in the urine and that there appeared to be a relation between the anomaly and the imbecility. This was the first demonstration of a metabolic error definitely associated with a form of mental defect and also with physical characteristics (blond hair and blue eyes). In phenylketonuria the subject is unable to oxidize a normally occurring essential amino acid (phenylalanine) to tyrosine at a normal rate. Because of this inability, phenylalanine accumulates in the tissues, rises in the blood stream, and spills over in the urine. This error also mobilizes other metabolic routes which normally play little part in the metabolism of these amino acids. In 1953 it was definitely shown that enzymic extracts prepared from the livers of phenylketonuric patients failed to further the oxidation of phenylalanine to tyrosine (Jervis 1953; Wallace, Moldave & Meister 1957). Extracts of normal livers do so quite readily. Furthermore, the use of radioactively labeled phenylalanine showed that the phenylketonuric can convert this phenylalanine to tyrosine at only a fraction of the normal rate. The most striking result of this deficient oxidation mechanism is the appearance in the urine of phenylpyruvic acid, a

compound which is readily detected through the greenish color it acquires when it reacts with ferric chloride. This provides a ready screening test for the deficiency in the newborn. The striking decreased pigmentation seen in phenylketonuria—blue eyes and blond hair—may be due to the decreased formation of melanin pigment, through inhibition of an enzyme known as tyrosinase. The abnormal metabolites of phenylalanine also apparently interfere with the synthesis of catecholamines important for brain functions. This may account for the lowered level of epinephrine and norepinephrine in the plasma of the phenylketonuric. Whether excess of phenylalanine or one of its breakdown products or an interference with some of the biosynthetic processes of catecholamines accounts for the mental defect remains uncertain. However, the concept opens up an inviting area for producing experimental phenylketonuria in the laboratory by means of "loading" the system with phenylalanine and also suggests a way of treating or preventing the disorder by withdrawing the offending amino acid from the diet.

The first attempt to relieve phenylketonuria by such dietary means followed only four years after the discovery of the syndrome (Penrose & Quastel 1937). A new approach to the problem was introduced in 1951, when, for the first time in the field of mental deficiency, diets specifically low in *one* amino acid (namely, phenylalanine) were introduced (Woolf & Vulliamy 1951). The so-called synthetic phenylalanine-low diets have now been used with varying success in a number of studies. They result in a sharp lowering of urinary phenylpyruvic acid and plasma phenylalanine. The patients so treated show a striking reduction in seizures and spasticity and increased responsiveness in motor development. There is also a darkening of the hair. Reversal to full phenylalanine natural diet leads to relapse. It has also become unambiguously clear that treatment must be introduced as early as possible and that improvement falls off sharply if this regimen is introduced beyond the stage of infancy. The developing nervous system is a vulnerable one. [See MENTAL RETARDATION.]

These studies are mentioned because in a sense they represent a prototype of approach which is now being applied, with some modest success, in other studies of the biological basis of mental disorder. The steps are as follows: An empirical finding—a deviant metabolite in urine—leads to a suspicion of a metabolic defect. The natural history of the disorder suggests a genetic basis for this defect. A biochemical lesion—a specific biochem-

ical defect—is defined. Since the metabolic pathways are interrelated, this single defect leads to consequences only indirectly related to the primary defect, yet very pertinent to the total pathology. The correction of the defect by reducing the metabolic load forms the basis of therapy. An animal model for this disorder is developed, and, finally, the fit of the model in terms of detection and prevention is tested.

However, there is still a large no man's land between evidence and inference. The effects of the deviant metabolites on the development of the nervous system, and particularly those areas concerned with perception, coordination, control of motor activity, and maturation of intellectual function, remain largely unknown.

Schizophrenic disorders

The facts cited above point to the complexity of the field of disorder when it is seen in terms of available biochemical facts and biochemical hypotheses alone. These complexities are compounded many times over in an attempt to relate known biochemical facts to the group of disorders known as the schizophrenias. It is by now generally accepted that we may be dealing, in this group, with a number of very different disorders, sharing a general symptomatology but quite possibly in need of a radical regrouping. The role of genetic factors is reviewed elsewhere [see MENTAL DISORDERS, article on GENETIC ASPECTS]. Careful genetic psychosocial studies of twins, on a national and international scale, are now proceeding, and such studies (particularly of families in which twins are discordant for schizophrenia) may contribute some of the facts which are needed to separate, on a conceptual basis, nature from nurture. Equally, careful longitudinal studies—prospective rather than retrospective—are needed (starting, preferably, in early infancy) to establish the role of genetic "givens" in the autonomic reactivity patterns which have been claimed to be deviant among schizophrenics. These suggest an instability of hormonal control and diminished compensatory physiological responses: peripheral vasoconstriction, capillary abnormalities in the nail bed, and abnormal pupil responses have been implicated as such signals. Yet the one measure which reliably distinguishes schizophrenic populations from normal is their state of readiness in the face of oncoming stimuli (Rodnick & Shakow 1940). This anticipatory set or "set index" suggests that in schizophrenia one may be dealing with a disorder of the attention process. How much this disorder represents the collusion between a genetically determined insta-

bility in homeostatic control and a defensive homeostatic withdrawal from stressful stimulus situations and thus, ultimately, a learned pattern of adaptation (enhanced, for example, by the double message structure found in schizophrenogenic families) still remains a matter of conjecture. [See ATTENTION; REACTION TIME; SCHIZOPHRENIA; STRESS.]

Nor does the difficulty of relating biochemical variables to clinical states end there. Even when the data are from the observation of schizophrenics in a hospital ward, there are a number of sources of errors which have seriously affected investigation (Kety 1959). These include long hospitalization, diet (including dietary iodine and protein deficiency), various therapeutic maneuvers (including medication), and the actual circumstances—stressful or otherwise—accompanying the drawing of the biochemical sample. Also, as in all other fields of psychobiology, subjective bias has cast a pall over many painstaking studies. All these reservations notwithstanding, there are, however, some findings largely attributable to the striking advances in present-day methodology. These advances are essentially three in number. First, the refinement of protein fractionation procedures (derived from the needs of blood transfusion and of plasma substitutes); second, the advance of microfluorometric techniques for the detection of very small quantities of catecholamines, indole derivatives, and their metabolites; and third, the development of radioactive tracer techniques and particularly the advent of the liquid scintillation counter, which makes it possible to follow a particular compound through a metabolic maze. As always, it is a moot question whether technical methods or intuitive insights are the more powerful propellants of science. Evidently, in our age they are inextricably connected.

In 1957 it was first reported that a serum fraction obtained from schizophrenic patients, when injected into carefully selected nonschizophrenic prisoner volunteers, led to the development of symptoms of thought disorder, autism, depersonalization, paranoid ideas, hallucinations, and catatonic stupor which were likened to schizophrenia (Heath et al. 1958). Attempts to replicate this finding by injection of material prepared according to similar instructions, however, were not successful (see Conference on Neuropharmacology 1959). This finding, however, seems to this writer less pertinent than the various lines of investigation which were stimulated by the finding. A number of groups have now independently obtained evidence which suggests at least the possibility that

an abnormal protein may be present to a greater extent in the blood of schizophrenics than in normals and that this substance may be capable of producing behavioral metabolic changes in some animal tests. There is also evidence that there is an antigenic abnormality in the pooled serum of chronically ill schizophrenic patients (Haddad & Rabe 1963) and that plasma from schizophrenic patients affects learning and retention of learning in the rat (Bishop 1963). Similarly, serum of schizophrenic patients has been shown to affect cortical (electrically evoked) responses of animals (German 1963). However, it is of more than suggestive significance that in these various studies plasma derived from normal individuals put under stress produced somewhat similar responses. It is therefore possible that one may be dealing here with a small molecular constituent liberated during stress and attached to one of the plasma fractions; the constituent may not be a unique characteristic of schizophrenia.

Another approach to the problem is the characterization of various serum protein fractions, rather than total proteins, in terms of electrophoretic and immunochemical properties. There is evidence from double-blind studies that there may be abnormal protein fractions in a considerable proportion of schizophrenic patients (Fessel & Grunbaum 1961).

A cognate approach to the above are the findings of another group (Frohman et al. 1960), who reported that when red blood cells of chickens are incubated with plasma or plasma fractions of some schizophrenic patients, there is an increase, compared with normal controls, of the lactate-pyruvate ratio. This finding, however, still awaits full confirmation, for the difference (in the lactate-pyruvate ratio) is seen only when the subjects have been engaged in moderate exercise before the blood samples are drawn. It may be that these serum factors, while responsive to stress in normals, may be greatly increased in schizophrenics subjected to stress. The serum factor apparently influences the stability of the red cell membrane, the rupture of which may alone account for the changes in the lactate-pyruvate ratio.

Broadly, then, the conclusion at this stage is that there is evidence of a plasma protein abnormality in schizophrenia capable of producing measurable behavioral, immunological, electrophysiological, and biochemical responses in suitable test preparations; and that this abnormal constituent may in fact contain a small molecular substance released by, or related to, physiological stress.

There are, however, a number of other small molecules which are increasingly being implicated

in the search for a biochemical factor (the so-called psychotoxic factor) in schizophrenia. As early as 1952 Osmond and Smythies pointed out that there is a close chemical similarity between the drug mescaline, derived from a Mexican cactus plant, and epinephrine and its precursor dopamine, both of which are usually found in the brain. Mescaline is a methylated derivative of dopamine. The mental changes produced by mescaline bear some resemblance to those seen in schizophrenia. The same paper concluded that "it is extremely probable that the final stage in the biogenesis of epinephrine is a transmethylation of norepinephrine, the methyl groups arising from methionine or choline" (a well-known methyl donor). It is just possible that a defective transmethylation of norepinephrine might lead to methylation of one or both of its hydroxyl groups instead of its amino group. This defective methylation could thus give rise to a mescaline-like toxic substance—Thudichum's "internally fermented psychotoxic." There is no denying the attractiveness of this hypothesis, for it relates the metabolism of epinephrine, a hormone liberated during stress, to the pathology of a condition in which stress tolerance and responsiveness to stress are markedly altered or reduced.

This suggestion that there may, in schizophrenia, be a disturbance of the transmethylation process is supported by the fact that a number of drugs (such as dimethyltryptamine, DMT) producing profound mental changes in man are in fact methylated congeners of normal body metabolites. On the basis of such findings it was indeed suggested by Hoffer and his colleagues (1957) that substances which would compete for methyl groups and act as methyl acceptors could competitively inhibit the abnormal process. The vitamins niacin and niacinamide are such substances, and some beneficial results following the administration of large doses of these vitamins in schizophrenia have been reported (Hoffer et al. 1957). These findings still await confirmation. A more direct approach to the problem was to administer large doses of L-methionine, a powerful methylating agent, and a number of other amino acids to chronic schizophrenic patients (Pollin et al. 1961). The changes seen in some patients following the administration of this material were striking; there was a brief and sharp intensification of the psychotic symptoms. This finding has since been confirmed by three other groups and suggests that methylation of aromatic compounds may indeed lead to substances which greatly affect brain function. Another piece of evidence along the same line is the reported occurrence in the urine of schizophrenic

patients of a substance 3-4-dimethoxy-phenyl-ethylamine (Friedhoff & Van Winkle 1962), suggested in 1952 by Osmond and Smythies as possibly an abnormally methylated and toxic metabolite. This compound is indeed the dimethyl derivative of dopamine, the precursor of epinephrine, and in structure is closely related to mescaline (the trimethyl derivative of this substance).

It is only fair to say, however, that the finding of this compound in urine is still subject to confirmation. The presence of the compound may be related to dietary factors and there is, so far, only preliminary evidence that the substance identified in the urine is indeed produced in the body. Once again, then, one can but say that we are at the beginning, yet the pieces are showing some fit.

Affective disorders

The relation of the midbrain structures and certain elements of the limbic system to the regulation of the visceromotor and affective states has already been mentioned. It is also clear that catecholamines and indoles play a dominant role in these highly specialized and all-pervasive regulatory centers.

The past few years have seen increasing evidence to suggest a possible link between affective disorders (i.e., depression or elation of mood) and changes in the metabolism of catecholamines in the central nervous system. Most of the evidence so far is inferential, yet the advent of pharmacological agents which strikingly affect mood by interfering with the storage, release, and disposition of catecholamines in the central nervous system and at peripheral sites has added an important segment to the body of evidence [See DEPRESSIVE DISORDERS].

Quite early it was reported, in a carefully controlled metabolic study, that clinical manifestations of periodic catatonic excitement and stupor were correlated with a change in the nitrogenous constituents of the urine (Gjessing 1938, Gjessing et al 1958). Longitudinal studies have shown that the urinary excretion of norepinephrine is increased in the manic phase and decreased in the retarded depression phase in manic-depressive ("cyclic") patients (Strom-Olsen & Weil-Malherbe 1958). Yet it is not clear whether this is only a small fraction of the total metabolites of epinephrine. However, it is now possible to study and identify most other biologically important products of epinephrine and to trace up or down a short list of catecholamine metabolites in man. Such studies of urinary metabolites in depressed patients and normal controls suggest as a tentative hypothesis that "some, if not all, depressions are associated

with an absolute or relative deficiency of catecholamines . . . at functionally important receptors in the brain" (Schulzberg et al 1962).

The major inferential evidence so far does not from physiological studies in the natural or treated states but from the results of pharmacological intervention. In this respect, three classes of drugs are of particular import, namely, reserpine (a major tranquilizer exerting its effect by depleting serotonin and norepinephrine sites in brain and peripheral sites); the monoamine oxidase inhibitors, which are powerful antidepressants and inhibit the destruction of naturally occurring amines (epinephrine, serotonin, and the like) by oxidation; and various imipramine-like compounds which, in a way not yet clearly understood, interfere with the local economy of catecholamines at intracerebral sites. Reserpine has been shown to induce severe depression in patients, yet where reserpine-induced depression is a valid pharmacological model of the naturally occurring condition state remains to be seen. In animals, reserpine induces sedation, which is associated with a decrease in the brain levels of norepinephrine, dopamine, and serotonin. The level of sedation correlates with the depletion of catecholamines in the brain and, furthermore, shows a rise in level of catecholamines with a return of normal motor behavior. Furthermore, the administration of dihydroxyphenylalanine and dopamine promptly reverse the reserpine-induced sedation in animals and return to normal behavior and norepinephrine release. An administration of the corresponding precursor (5-hydroxy-tryptophan) does not in animals. Dopamine has been reported to counteract the sedating effect of reserpine. Thus catecholamine depletion (i.e., depletion of dopamine, epinephrine, and norepinephrine) may be of major importance in reserpine-induced sedation in animals. Reserpine-induced depression in man may be on a similar basis.

The gross picture is reversed for the antidepressive agents. Administration of monoamine oxidase inhibitors, such as iproniazid, and other effective antidepressives both produced behavioral excitation in animals and correlated well with elevated levels of brain norepinephrine. Amphetamine stimulation is less related to an elevation of brain serotonin. The mood-elevating properties of amphetamine, benzphetamine, and amphetamine have been attributed to the release of catecholamine from its storage sites. The "rebound" effect following amphetamine administration (which shows clinically in depression reflected in a temporary depletion of catecholamines)

IV EPIDEMIOLOGY

"Epidemiology" refers to the science which studies "the mass phenomena of disease" (Greenwood 1935) by determining the distribution of conditions or diseases and the factors which determine these distributions (Lilienfeld 1959); that is, it is "the study of the distribution and determinants of disease prevalence in man" (MacMahon et al. 1960). The analysis that epidemiology makes of these findings results in a "medical ecology" (Gordon 1952). Epidemiology relates observed distributions of disorders to the environments in which people live—the physical, biological, and social environments.

"Mental disorder" is used in this article to refer to the full range of psychic conditions identified by psychiatrists or competent social authorities as abnormal or needing improvement. This is a broader range than would be used in planning or conducting any single inquiry but permits consideration, where necessary, of studies of delinquency, criminality, military desertion, and group fads (such as fish swallowing), as well as any conventional psychiatric diagnostic category or an individual symptom or special syndrome recognized in psychiatry.

Uses of epidemiology

Seven uses of epidemiology can be distinguished (Morris 1957): (1) knowledge regarding *historical trends* helps to distinguish disorders that are on the increase from those that are disappearing; (2) *community diagnosis* of the size, location, and distribution of a condition aids in planning health programs for the community; (3) from accumulated records of the ages at which individuals contract a disease, *individual risks* can be calculated (a basic tool in calculating insurance premiums), and knowledge of contingency risks aids in estimating the effects of host factors in determining the distribution of cases; (4) knowledge of the attributes of cases not in treatment *enlarges the clinical picture* by making our concept of a disorder less dependent on the clinician's limited perspective on cases; (5) occasionally, new *syndromes* are identified because clinically dissimilar

cases are found to arise from a particular common background or because clinically similar cases are found to arise in two or more distinct sets of circumstances; (6) the *working of health services* can be studied in terms of their successes and failures, their selection of cases for treatment, and their deleterious effects on the people they seek to serve; and (7) in the *search for causes* of disorders, data on the factors associated with the distribution of a disorder supplement laboratory and clinical data in the elucidation of causal mechanisms—at times the crucial breakthrough in our understanding of the way in which a condition is caused is made by epidemiological inquiry (this occurred with cholera, pellagra, and lung cancer).

Historical trends. Historical trends are important but difficult to study. The Group for the Advancement of Psychiatry reviewed psychiatric knowledge recently (1961). The use of old data gathered for another purpose is sometimes tried. It is difficult to identify two groups at two different points in time which can be considered different time samples of the same population. If the questions are asked broadly enough and if the population being considered has some sort of continuing dimensions, an approximation of trends can sometimes be established. Two studies are noteworthy because they are particularly well done.

Goldhamer and Marshall (1949), in a superb study of the admission of psychotics to mental hospitals in Massachusetts during a hundred-year period, found evidence to contradict the widely held view that schizophrenia is becoming more common. In spite of the work's excellence, the implications of the findings remain uncertain, mainly because the data depend entirely on records of cases admitted to mental hospitals and because the population "sample" was taken from an area (Massachusetts) that was the first in North America to be industrialized and was subject to gross emigration and immigration during the time period observed.

With the hope of showing that an inverse relationship between intelligence and fertility was leading to a decrement in the national average intelligence quotient (IQ), a survey of Scottish intelligence tested "all" 11-year-olds on one day in 1930 and repeated almost the same procedure on one day in 1949. The findings were negative, according to the publications (Scottish Council for Research in Education 1953), but reinterpretation of the differences between the methods used in the two surveys suggests that the prevalence of very low scores among Scottish 11-year-olds may actually have decreased (Gruenberg 1964).

Community diagnosis. Many studies of particular communities have been carried out for diagnostic purposes; some outstanding examples are mentioned later in this article, in the section on case-finding methods. Since community diagnosis, by its nature, is done for a particular community, it is no more reasonable to borrow the diagnosis of one community and apply it to another than to borrow a neighbor's X ray because he had a similar cough. The general picture will be more or less the same, but the details which differentiate one community from the other may be crucial. Techniques for making rapid and relevant surveys of communities to aid mental health planning are sadly lacking. A few demographic facts are often used (as in the American Psychiatric Association's consultations) to infer what the findings would be.

From the health service's point of view, enumeration of cases that do not distinguish preventable or curable conditions from nonpreventable or noncurable cases are of little value. One learns only that the problem is small, big, very big, or enormous, depending on how one defines the problem. The American Public Health Association's *Mental Disorders* (1962) is a milestone because it indicates the conditions for which it is currently important to be able to enumerate cases. As the technology of treatment and prevention grows, this list will grow. This analysis also indicates that the social-breakdown syndrome is important in evaluating the benefits of a comprehensive community mental health service (e.g., Gruenberg 1966). Similarly, future studies for community diagnosis, as well as for analysis of health services, will require techniques for counting cases of conditions for which something can be done.

The calculation of individual risks. The risk of a child's being Mongoloid is dependent on its mother's age at the time of birth, but not its father's (Penrose 1949). If a woman has German measles while pregnant, there is an increased risk of her child's being brain-damaged; this increased risk is highest if the infection occurs during the third month of pregnancy (Hill et al. 1958). If a young child is removed from his parental home for months, there is an increased risk of nightmares, bed-wetting, and some other neurotic symptoms; if the mother leaves the child's home for several months, the increased risk is much less or nonexistent (Douglas & Blomfield 1958, pp. 112-113).

Calculating individual risks is frequently helpful; it should not be confused with measuring the incidence of a condition (number of new cases arising during a unit of time in a defined popula-

tion, divided by the number of people in the defined population), or with measuring the prevalence (number of cases present at one point in time in a defined population, divided by the number of persons in that population at that point in time).

Enlarging the clinical picture. The clinical picture of a condition is almost automatically enlarged by follow-up studies. Follow-up studies of persons identified at about the age of 12 or 13 as mentally retarded are needed now because many cross-sectional prevalence studies have shown an age distribution of cases indicating a rapid fall in prevalence after age 14 that is incompatible with the definition of the condition, which includes the concept of a fixed, permanent state. [See MENTAL RETARDATION.]

The Medical Research Council Unit for Research on the Epidemiology of Psychiatric Illness provides psychiatric care in a general hospital ward in Edinburgh to which are routinely brought, regardless of severity, all self-poisoning cases in the city of Edinburgh. This comprehensive experience has made the clinicians aware of self-poisoning cases with intent at self-destruction by people who do not exhibit evidence of any psychiatric disorder; they find that the severity of need for psychiatric attention has no relation to the probability that the self-poisoning would lead to death. Thus, looking at all cases of self-poisoning is beginning to provide a different picture of the range of clinical findings.

Syndrome identification. The study of population distributions of cases resulted in separating typhus ("jail fever") from typhoid (water- and food-borne). Psychiatry has not made progress this way. Yet, certain diagnostic categories have been set up in terms of the age or personal characteristics or situations of the cases (e.g., involutional melancholia, combat fatigue, dementia praecox, senile dementia), such a classification short-circuits epidemiological inquiry. The course of disorders has been a key criterion in characterizing manic-depressive psychoses, dementia praecox, and mental retardation. Patients discourteous enough to violate the rules have simply had their diagnoses changed. Such practices hinder progress. "Puerperal psychoses" have been in and out of fashion, but pregnancy has not yet been shown to be associated with psychoses (Pugh et al. 1963). Involutional melancholia is confined to certain age levels and is out of favor at present. These illustrations indicate the special problems of classification in psychiatry, where entities like the Ganser syndrome in prisoners and combat fatigue in soldiers gain currency in each generation.

The social-breakdown syndrome is a new sociogenic entity. Its identification arose from observations that can be loosely termed clinical epidemiology (Pickles 1939). A community served by a single mental hospital that undergoes radical reform of patient care and breaks down barriers between hospital and community services stops producing new cases of severely deteriorated, helpless, vegetating individuals. Similar reforms elsewhere lead to similar observations.

As a result of these observations, clinicians with a broad (population) perspective change their views of the disorders. Disturbances in capacities to fill social roles come to be seen as extrinsic to the mental disorders of the patients and of secondary importance in comparison with the society's customs and attitudes regarding mental disorders which result in rejections and degrading behavior toward the ill. This sequence of observations leads to a reformulation of clinical syndromes that puts together manifestations previously thought to be due to several different disorders and that attributes these manifestations to a series of particular social events likely to occur in the presence of any of these disorders.

Like any other conclusion derived from unsystematic observations, it may gain currency because it fits the prevailing preconceptions of many people, without being further established. Unless systematic evidence is obtained, its validity remains untested.

The new sociogenic social-breakdown syndrome is best examined as a promising hypothesis. In order to test the sociogenic hypothesis, the syndrome must be defined operationally and case-finding techniques developed. These must be kept separate from the specification of the social conditions suspected of favoring the syndrome's appearance. Recent investigations have shown that these are soluble problems and confirm the hypothesis in large part; further investigation will also make clearer which mental disorders make people particularly susceptible to the noxious social forces [Gruenberg 1966; see also *PSYCHIATRY*, article on *SOCIAL PSYCHIATRY*].

Working of health services. Much of the data gathered on the distribution of mental disorders can be studied to help us understand how hospitals and clinics work. This can be a productive approach to data gathered for other uses. When a population is surveyed for cases similar to those that have gone to a hospital, many unhospitalized cases are found. This suggests that social forces control admissions; if so, these social forces may account

partly, or entirely, for variations in admission rates. This proved to be a productive hypothesis in studying the distribution of admissions for the elderly (Mental Health Research Unit 1959-1960) and could be used to interpret many findings (e.g., Faris and Dunham 1939; Goldhamer and Marshall 1949). Readmission rates can also be looked at this way. Freeman and Simmons (1963) found that the types of homes to which mental hospitals released patients did not affect the probability of return to the hospitals; from this they concluded that reasons for rehospitalization are unrelated to the social environment. However, the same data can be approached by starting with the assumption that a hospital staff releases only certain patients and, in deciding which to release, takes the family situation into account; if this is true, the data can be used to argue that the observed lack of difference only shows that the various staffs are equally competent in evaluating the suitability of different types of homes for their patients.

Thus, the plan to see whether variations in home living arrangements affect the probability of rehospitalization by studying a cohort of patients released from hospitals to varying home situations is irrelevant to the question. The plan is suitable for an evaluation of the hospitals' release policies with regard to different types of home situations. Obviously, volunteer subjects cannot be assumed to be randomly selected subjects; it is just as important—but sometimes more difficult—to perceive that subjects have been selected by someone else or by some agency. It is necessary to realize that when a bureaucracy selects subjects, the data reflect the behavior of the bureaucracy. The same principle applies to analysis of first mental-hospital admission rates.

Preventive trials. The most important studies of health services are those which are carried out in the form of a preventive trial when the health services seek to prevent a particular disorder. The population given the service is selected so that there is a comparable control population to whom service is not given (Pasamanick et al. 1964). The study then becomes a crucial experiment for the health service; it can also be a crucial experiment, if all goes well, for testing an etiological hypothesis. The preventive trial is often thought to represent the last stage of inquiry and to be justified only when much other evidence has been accumulated. But when the preventive procedure advocated is believed to be harmless and generally thought to be desirable and when its supply cannot satisfy all demands, the preventive trial is justified

even if prior evidence is very weak. It is wrong to assume that preventive trials are inherently more expensive, more dangerous, or more difficult than passive studies; such research can be easier and cheaper. However, creating the opportunity for preventive trials and ascertaining that the design of the study is being adhered to throughout pose difficult problems.

The search for causes. Each use described above generates data with implications for causes.

Outstanding today are the efforts to identify the mechanisms which lead to what Pasamanick has called the "continuity of fetal damage," ranging from death to mild brain damage followed by reading disabilities, impulsive behavior disorders, and other syndromes. Fetal damage has been linked to rubella, to the effects of poverty, and to early complications of pregnancy. Several lines of evidence suggest its linkage to very mild or moderate malnutrition of the mother during the first few months of gestation (MacMahon & Sowa 1961).

The hypothesis of schizophrenogenic mothering is being pursued (Lidz & Fleck 1960). Current work is clarifying the nature of the hypothesis and may do more [see SCHIZOPHRENIA].

Maternal deprivation, as Bowlby (Bowlby et al. 1956) named a hypothetically pathogenic experience, has been investigated a number of times (e.g., Douglas & Blomfield 1958). These studies, like those of Pasamanick, not only look for causes but relate dissimilar clinical syndromes to one set of causes. Many investigations are required before the relationships become clarified and before the credibility of the hypothesis can be appraised. Bowlby's own study has weakened the initial hypothesis. Hunt (1965) has recently pointed to some further weaknesses in the hypothesis [see INFANCY, article on THE EFFECTS OF EARLY EXPERIENCE].

Down's syndrome (Mongolism, trisomy-21) is not only a major cause of serious mental handicap, but the new and growing knowledge regarding the associated chromosomal abnormality supports the notion that some particular cause or group of causes must be at work and that other chromosomal abnormalities may have the same causes. It is complicated to investigate these conditions, and social phenomena have not yet been implicated.

Too often efforts to find the determinants of the distribution of a mental disorder are launched as one-shot investigations, without the researchers' knowing what the distribution of cases is. This procedure assumes that if the distribution is found to be that predicted in the hypothesis, then the hypothesis has been proved, and if not, then it has been disproved. Such a course is not absolutely

doomed to failure, but it is not likely to lead to the gathering of data that can rule out alternative explanations of the observed distributions.

Tools and techniques

Case finding. Hospital and state school records, clinic outpatient records, records of private practitioners, and key-informant methods have all been used repeatedly in case finding.

Hospital records have been used to study first-admission rates in relation to various hypotheses. Faris and Dunham (1939) pioneered the analysis of first-admission rates in terms of the modern social ecology of a city. Using the census-tract classification of Chicago, based on the University of Chicago sociology department's methods of characterizing urban land use, they allocated the first admissions to mental hospitals to the census tract of origin. They predicted correctly the now well-established fact that the first-admission rates for schizophrenia are highest in the central, deteriorated section of the city and decline with the distance of neighborhoods from the center. This was a startlingly successful fusion of Durkheim's ideas, urban sociology, and a hypothesis about the social origins of schizophrenic syndromes. Even more startling were the failure of manic-depressive psychoses to fall into such a pattern and the existence of a different pattern for organic psychoses. These different patterns tend to confirm the importance of the psychiatric diagnosis in spite of the skepticism of many psychiatrists regarding the objective nature of their diagnoses.

These findings have been confirmed in other cities. A literature has developed seeking to account for the high first-admission rates of schizophrenics from the city's center. The straightforward notion that the depersonalized socially isolated part of the city favored the development of schizophrenic disorders has not been universally accepted. Attempts to demonstrate that the disproportionate concentration of schizophrenic cases coming to hospitals from the central part of the city is due to consequences of schizophrenic disorders rather than the pathogenic nature of these neighborhoods can be thought of as studies of the "drift hypothesis." This states that schizophrenics tend to drift into the rooming-house areas of cities at a higher rate than do other people, producing the concentration of cases found there.

Sanua (1963) points to the main studies of this hypothesis and to the conflicting evidence, citing Morrison's (1959) finding that patients had a lower social-class status than their fathers, whose social-class distribution was similar to that of the

general population. The inference that schizophrenia causes downward social mobility does not necessarily follow from this observation; since occupational levels tend to rise with age, schizophrenics may accumulate in lower occupational categories because they fail to climb the occupational ladder as fast as other young people.

If downward mobility (or failure to rise with one's generation) is really at the root of the phenomenon, then the etiological theory advanced by Faris and Dunham does not hold. Their observations would remain, however, and require explanation.

A more recent study, *Social Class and Mental Illness*, by Hollingshead and Redlich (1958), found that in New Haven the prevalence of treated cases was related to social class. The authors asserted that their data show a gradient of prevalence rates which falls from a high rate in the lowest social class to a low rate in the upper social classes. Miller and Mishler (1959), however, state (correctly, I believe) that the New Haven data show only a very high rate for the lowest social class and that the observed figures in other classes do not demonstrate a gradient of rates.

The difficulties of interpreting such studies are compounded by the reliance of the studies on clinical records of cases in treatment and by the social factors affecting hospital-utilization patterns. To obviate the weaknesses of relying solely on clinical records, a method centering on a structured household-interview questionnaire derived in part from the Cornell neuropsychiatric inventory has been developed; this method has not yet been systematically calibrated (Macmillan 1959), but it holds out a promising potential. Its first important use for case finding on a large scale was by Stouffer (Stouffer et al. 1949) in World War II. It was one of the methods used in the first large-scale metropolitan survey, the Midtown Manhattan Study (Langner & Michael 1963).

One population of over two thousand has been personally interviewed by psychiatrists at both the beginning and the end of a decade (Essen-Möller 1956). Participant-observers with a psychiatric background have been useful (e.g., Eaton 1955).

Finding cases of severe deterioration (severe social-breakdown syndrome) has been carried out by means of a semistructured interview by specially trained public health nurses, psychiatric social workers, and graduate behavioral-science students. Another method involves interviewers' filling out structured questionnaires—together with answers to open-ended questions—after they have been trained to complete the protocols following open-

ended interviews; these protocols are then evaluated by psychiatrists, who categorize the individuals (Mental Health Research Unit 1959-1960). A method similar in principle was used in the following years in the age groups under 60 in Stirling County and in midtown Manhattan (A. Leighton 1959; Hughes et al. 1960; D. Leighton et al. 1963; Langner & Michael 1963).

Cases derived from nonmedical-service-agency records were identified by Lemkau and associates (1941-1942) in the Eastern Health District in Baltimore and in the survey of the mentally retarded in Onondaga County, New York State, by the Mental Health Research Unit staff, under the direction of the program director (Goodman et al. 1956). All of these are useful devices. In practice all are complicated to use and none are easily applied with precision and accuracy. None of them have been adequately calibrated against a standardized ultimate criterion. Such a criterion requires a set of explicit objective criteria for identifying a case, a standardized method of observation, and an estimate of observer variability (Cochrane et al. 1951).

The methods of household sampling of populations, highly developed by social scientists, have been used in a number of studies; their most extensive use currently is in the continuous National Health Survey (U.S. National Health Survey 1958).

Sorting populations. The use of statistical techniques in planning and interpreting studies has developed to a very high level, borrowing from general statistical theory, agricultural research, genetic research, social science, and economics. Epidemiologic inquiries have contributed devices for age standardization and for adjustment of data, which have in turn been used by those fields (Hill 1937).

The study of case aggregations in neighborhoods, households, and families has developed a whole series of techniques. Some of these depend on the concept of primary-case (or proband) rates and secondary-case rates. In the study of mental disorders this has been most frequently associated with genetic hypotheses, and in these instances the concept of lifelong expectation of manifesting the disorder has been developed. In this field the formulas of Wilhelm Weinberg and the mathematician G. H. Hardy (1908) and of Stern (1943) are particularly appropriate. They depend, however, on estimates of differential death and migration rates, whose validity is hard to judge from existing data. The study of familial and household aggregations is not confined to genetic hypotheses, however, as is shown in a review of the literature

(Gruenberg 1950) and by Bleuler's review of studies on schizophrenia (1955); a review of the knowledge regarding group disorders together concepts from psychiatry, social psychiatry, and social psychology (Gruenberg 1957).

Populations have commonly been characterized by age and sex and time ever since the Hippocratic writings on times, places, and persons. Variations in incidence and prevalence rates by age and sex are frequently interpreted as though age and sex were causative factors. Generally they are not mechanisms by which disorders are produced but convenient ways of classifying populations which develop disorders at different rates. The suspected mechanisms which are distributed according to age and sex also need to be looked into, as was done recently by Langner and Michael (1963). Categorizing the population according to previous illnesses is a frequent but not highly standardized procedure. Except for body typing, the categorizing of populations according to physical characteristics has not been used in inquiries regarding mental disorders. Studies attempting to link genetic characteristics to certain disorders have focused on blood types. It is to be expected that in the next decade other physical characteristics will prove relevant to mental disorder epidemiology. Categorizing populations by their social characteristics is almost standard nowadays in epidemiological inquiry in all fields. The social environment has usually been regarded as important by epidemiologists, and this recognition has been increased greatly by advances in methods of characterizing socioeconomic status and other social variables. The complexity of socioeconomic classifications in a rapidly changing society has made this type of categorizing hard to standardize; attention will probably become more focused on specific characteristics of individuals, some of which are incorporated into indices of socioeconomic status. One study showed that hospital-admission rates for elderly persons were unrelated to economic levels of neighborhoods but were closely related to the frequency of multiple-family dwellings in neighborhoods; yet no correlations with socioeconomic status (a composite index) could be found [see Gruenberg 1953; see also AGING].

The conduct of studies. The list of references makes it clear that contributions to the epidemiology of mental disorder have been made by workers with various professional backgrounds; there is no reason to expect this to be altered in the future. Technical expertness in such work does not develop from any one course of professional training but is acquired by experience in conducting and inter-

preting the findings of investigations. Too many investigations have been conducted with the hope of testing a hypothesis about the determinants of the distribution of a disorder in a single investigation. The opportunity for refining a hypothesis and going back with experienced investigators to the same population rarely occurs. But such steps can be expected to yield larger returns in knowledge than a proliferation of single investigations. These defects in the social organization of research are being rectified by the creation of permanent laboratories for conducting investigations.

The first such laboratory was created at Syracuse, New York, in 1950, on a pilot basis, by the New York State Department of Mental Hygiene and was made permanent in 1955. Since then the Medical Research Council of Great Britain has created one in the University of Edinburgh department of psychiatry; the Danish government has set up one at Aarhus; and the Swedish government, one at Lund. The U.S. National Institute of Mental Health finances one at the Columbia University department of psychiatry.

These improvements in social support should lead to a more rapid exploitation of advances as they are made and thus should speed up the acquisition of knowledge. But it is to be expected that a larger number of contributions to our understanding of mental-disorder epidemiology will continue to come from workers who are not labeled epidemiologists and who will in many instances not regard their work as particularly relevant to mental health. The epidemiologist will continue to be interested in getting answers to his questions and will, hopefully, judge new contributions on their merits rather than on their author's school of thought or previous conditions of servitude (i.e., degree sequences).

In the context of this encyclopedia it may be well to point out that *all* disorders, whatever the causes, have distributions that reflect social factors. This universal proposition follows from the simple fact that all classes of causes have such social distributions.

For example, Goldberger (1964) showed that pellagra is due to a nutritional deficiency by studying its incidence in different social groups in southern mill towns. MacMahon and Koller (1957) showed that the higher leukemia death rate among whites, as compared to nonwhites, may well be due to more exposure to diagnostic radiation among Jews (who apparently use medical specialists at a higher rate). Gelfand and his associates (1957) showed that naturally acquired immunity to polio viruses occurs at early ages most frequently in

low-income groups. Böök (1961) reviewed accumulations of genes in particular linguistic and social groupings.

Roueché (1954) describes how poisons can spread through socially isolated parts of a population.

Sometimes the social forces are considered the main factors (as in "diseases of poverty" and in "diseases of affluence," such as coronary heart disease) and sometimes the intermediate variables that help unravel the chain (as in pellagra). But in understanding every distribution of disorders, knowledge of social forces plays some role.

Early conceptions of mental disorders in children are reflected in several clinical papers on child-rearing practices from the sixteenth, seventeenth, and eighteenth centuries (see Kessen 1965). These precursors of present ideas about causality failed to receive widespread acceptance and scientific interest, however, until recently. Even Kraepelin's influential *Psychiatrie*, first published in 1893, did not discuss mental disorders in children in any of its many editions. Scientific interest in deviant mental processes in children has flowered in the twentieth century, stimulated in large part by theories of mental functioning advanced by Freud, Piaget, Watson, and others which emphasized developmental and dynamic factors as well as notions of environment causality and learning. Further, interest in mental disorders in children has increased with the resurgence of scientific interest in children's behavior in general in the twentieth century, particularly since the late 1940s.

Resources for the diagnosis and treatment of mental disorders in children have multiplied in the United States and in Europe since the 1950s. In the United States, the establishment of the National Institute of Mental Health and the National Institute of Child Health and Development and the allocation of federal funds for the development of plans for organizing and providing comprehensive mental health services in local communities have stimulated the growth of relevant programs of service, professional training, and research. A federally supported conference of professional organizations and interested agencies was held in 1964 to insure and to plan for the provision of diagnosis and treatment of mental disorders in children under federally sponsored community health programs (American Psychiatric Association 1964).

Definition, predisposition, precipitation. The definition of disorders of mental functioning in children varies depending upon one's conception of mental functioning in general. Most professionals—including psychologists, psychiatrists, and social workers—with special training in the diagnosis and treatment of mental disorders in children currently emphasize a multidimensional approach. This approach encompasses psychosomatic considerations, developmental capacities and vulnerabilities; constitutional and genetic factors, the internal personality system, including cognitive, perceptual, and affective mechanisms and the fluidity and plasticity of the child's personality

characteristics; and psychosocial considerations, including parent-child relationships, family interactions, and sociocultural influences. This approach also stresses the need to assess and capitalize upon the healthy and adaptive facets of the child's personality.

A conceptual framework which encompasses all of the above aspects of the child's functioning inclusively and systematically has not been developed. However, the Committee on Child Psychiatry of the Group for the Advancement of Psychiatry has prepared (in unpublished form) what appears to be the best available approximation of such a framework (Committee on Child Psychiatry 1965). The present discussion of mental disorders in children leans heavily upon its work.

Mental disorder can be defined as a failure in the child's attempt to maintain an adaptive equilibrium between physiological, psychological, and interpersonal systems; there is a close relationship between physical and psychological factors. In the child with certain constitutional or experiential predispositions, disordered mental functioning may be precipitated and sustained by physical, psychological, or social stimuli.

Biochemical stimuli or stressful insufficiencies of chemical substances may disrupt the child's physiological equilibrium as well as associated perceptual, cognitive, and emotional systems. In addition, the child's restitutive efforts involve an interaction between physiological, psychological, and social systems.

Stimuli of a psychological nature may also precipitate mental disorder. Such stimuli include conscious or unconscious thoughts and feelings which arouse anxiety in the child because of their association with stressful past or present experiences. They involve the cognitive system in that they are represented in symbolic form in memory and thinking, and the perceptual apparatus. Thoughts, memories, and feelings triggered by anxiety-arousing psychological stimuli lead to the child's employment of psychological defenses or compensating behaviors as he seeks to avoid a breakdown in adaptation or equilibrium.

Stressful social stimuli in the child's environment may also precipitate disorder. Such stimuli include the loss, or threat of loss, of close interpersonal relationships and the frustration of basic needs resulting from disturbances in relationships within the family.

The nature and severity of the mental disorder precipitated by physical, psychological, or social stimuli, or of interactions among them, is contingent upon the stressfulness of the stimuli as well

as upon genetic and constitutional factors (for example, temperament, body build), previous experience, and the developmental level of the child. Stressful stimuli initially disruptive of one of these systems may, and often do, have repercussions in other systems. Thus mental disorders in children may be precipitated by disruptions of a physical, social, or psychological nature, but the child's defensive efforts or attempts at restoration of ego functions or compensatory behavior almost always involve all three systems. For example, a stressful thought or fantasy may lead to emotional conflict which triggers "signal anxiety." This signal, warning of possible breakdown in adaptation or mental equilibrium, leads to the establishment of psychological defenses or adaptive interpersonal behaviors. If emotional conflict and anxiety are severe or become chronic, physiological concomitants may develop. Such physiological symptoms are reversible if the underlying emotional conflicts are resolved; chronic unresolved conflict and anxiety may lead, however, to serious strain and even breakdown of weakened physiological systems or organs. [See ANXIETY; CONFLICT, article on PSYCHOLOGICAL ASPECTS; STRESS.]

In the first several months of life the immaturity of the physical and mental systems results in the infant's responding in a global manner to lack of gratification of his needs or to stressful stimuli. The very young infant shows little differentiation of emotional response; he tends to respond to stressful stimuli with general symptoms of distress (for example, crying, global motor activity). However, there is increasing evidence of systematic individual differences in response even at this early level of development (Murphy 1962). Individual differences in stress thresholds, modes of expressing distress, and secondary reactions to distress—including the number of organ systems involved and the intensity of their involvement—may be prognostic in infants of a predisposition to mental disorder in later childhood (Korner 1964).

In children predisposed by stressful experiences and by personality structure, continued emotional conflict may lead to the chronic use of psychological defenses and maladaptive social behaviors known as symptoms of mental disorder. Particular constellations of such symptoms define the different types of mental disorder in children. In general, these clusters of clinical symptoms can be assigned to one of three general divisions: psychoneuroses, personality or character disorders, or psychoses.

Some of the physical or psychological symptoms in each cluster may result from the child's attempt to maintain equilibrium or adaptation in the face

of current stressful events or to compensate for the disturbance, to make restitution, or to obtain gratification of physical, psychological, or interpersonal needs. Other symptoms in each clinical picture may define the new equilibrium resulting from the child's adaptive and compensating efforts. They may include partial restriction or malfunctioning of perceptual, cognitive, social, or physiological functions, rigid reliance upon defense mechanisms such as repression and denial, or a more severe breakdown in adaptive efforts.

Anna Freud (1965), Erik Erikson (1950), and many others have emphasized that in addition to the physical and personality characteristics and the experiences of the child, it is important to consider both his developmental level and "lines" or continuities of development. Thus, the notion of a state of psychological equilibrium in the child is only a relative one, with such states stable and definable only at cross-sectional points in time during his growth. These "states" interact systematically, and lines of development such as that from "dependency to emotional self-reliance and adult object relationships" may be observed (A. Freud 1965).

Interpersonal or psychological events may have stressful effects upon a relatively immature mental apparatus, whereas the same stimuli may be handled without disruptive anxiety by an older child or adult. In addition, the child may defend against anxiety resulting from such stimuli through regression to a more immature level of adaptation. Or, such stimuli may reinforce fixations of personality development which partially preclude further development in one or more areas of functioning (for example, learning). Thus the child's developmental level partially determines his capacities and modes of coping with potentially stressful stimuli of a physical, social, or psychological nature and partially determines the type and severity of mental disorder. For example, certain intrauterine viral infections during early pregnancy are more likely to produce congenital anomalies than such infections occurring later in gestation. In addition, a prolonged lack of adequate mothering is particularly damaging to infants in the second half of the first year. The research of Spitz (1946), Bowlby (1960a; 1960b), Provence and Lipton (1962), Piaget (Flavell 1963), Escalona and Heider (1959), and Heider (1960), as well as recent animal research by ethologists (Ostow 1959), suggests that serious and perhaps irreversible defects in social and intellectual development may follow if the child fails to receive sufficient interpersonal or perceptual stimulation during appropriate develop-

mental phases, including those of early infancy. Such defects may predispose the child to one or another type of mental disorder, but knowledge of the specific nature of such relationships depends upon future research. [See INFANCY, article on THE EFFECTS OF EARLY EXPERIENCE.]

Freud's concept of emotional conflict as amplified by Anna Freud, Hartmann, Erikson, and others is central in contemporary theories of mental disorder in children, particularly with respect to the development of psychoneuroses. As the infant or preschool child develops relationships with people and as his mental functions become more complex, he may show a variety of *reactive disturbances* in behavior, such as temper tantrums, aggressive behavior, and crying. These disturbances are reactive to environmental stress, primarily conflicts with parents over the control (socialization) of basic sexual and aggressive drives, and are the early precursors of internalized emotional conflict. In the early years, these disturbances are generally transient and reversible in response to positive changes in the environment, although as a result of continued disturbances in parent-child relationships, they may become chronic and fixed. Reactive disorders are also seen in the older child; the symptoms may include anxiety, unrealistic fears, shyness, feelings of inadequacy or loneliness, disturbances in attentional processes and learning, and inappropriate social behavior.

If the child's emotional conflicts are especially anxiety-arousing and unresolved, they later lose their conscious nature and are repressed and internalized. The conflicts are then inaccessible to further attempts at resolution, including new efforts made possible by the development of more powerful and complex cognitive and other ego functions: the capacities for greater independence in the gratification of needs, a longer attention span, improved reality testing, increased ability to think abstractly as well as concretely, and further differentiation and integration of perceptual and motor functions—together with further differentiation of the emotions, more effective repression of anxiety and other affects, and the internalization and symbolic representation of conflict. Because of their relative inaccessibility to conscious problem-solving efforts, emotional conflicts in the child may become self-perpetuating and lead to the establishment of chronically maladaptive behavior learned in early periods of development.

Depending upon his experiences and his own developmental capacities, however, the child may instead resolve conflicts established earlier, or a new conflict facing him in a crisis situation, and

thereby achieve a higher level of differentiation and structure of personality. If such resolution and mastery is prevented, temporary regression, long-term arrest in cognitive or emotional function and development, or decompensation or adaptive failure may occur. Thus, unconscious conflicts, with associated alternating experiences of anxiety and employment of maladaptive psychological defenses, may become firmly established components of the personality, leading to structural rigidity and brittleness and presenting the model of psychoneurosis in the child.

Psychoneurotic disorders. A variety of symptoms and patterns of symptoms may be observed in the psychoneurotic mental disorders of children. These symptomatic reactions to neurotic conflict may fluctuate and change with changes in development and socialization. The psychoneuroses are not characterized by extreme personality disorganization and grossly distorted reality testing. Although psychoneurotic symptoms of internalized emotional conflict may be observed in children as young as three or four years, fully structured neurotic disorders are not ordinarily seen in children until the early school-age period. The typical childhood neurosis develops in a youngster who has already evolved a conscience or superego, who has achieved an internalization of conflict and the use of a variety of defense mechanisms, including repression of affects from consciousness, and who manifests symptoms symbolically relevant to the underlying conflicts. Several relatively independent types of psychoneurotic disturbances in children have been defined, including anxiety, phobic, conversion, dissociative, obsessive-compulsive, and depressive disorders. Detailed descriptions of these disorders are discussed elsewhere [see ANXIETY; DEPRESSIVE DISORDERS; OBSESSIVE-COMPULSIVE DISORDERS; PHOBIAS; see also Committee on Child Psychiatry 1965].

The well-known cases of "Frankie" (Bornstein 1949) and "Little Hans" (Freud 1909) are illustrative of the phobic type of neurotic disorder in which the defense mechanism of *displacement* is prominent. Here the child unconsciously displaces the meaning or content of the underlying emotional conflict onto an object or situation in his environment which is symbolically relevant. The fears derived from the internalized conflict are experienced in a distorted and irrational manner. The child avoids stimuli which reactivate or intensify his displaced conflict, and he often projects his sexual, hostile, and other unacceptable feelings onto the external feared objects such as animals, dirt, elevators, or situations such as school. Mild

and transient fears, fearful reactions to stressful experiences (reactive disorders), and common developmental crises involving separation anxiety in children should be carefully distinguished from phobic psychoneurotic disorders, with their internalized and structured nature. [See DEFENSE MECHANISMS.]

Remission of symptomatic behaviors without treatment may be observed in some of the milder psychoneurotic disorders as the child masters the developmental tasks and crises of later stages (Nagera 1966). However, such disorders ordinarily require psychotherapeutic intervention with the child and his family. The prognosis for response to treatment is good. Treatment requires assessment of the balance of external and internal forces involved in the disorder (Haworth 1964). Depending upon the balance of such forces, therapeutic intervention may be made primarily through manipulation of the environment, or the therapist may focus upon achieving intrapsychic changes in the child and other family members, leading to the resolution of interpersonal conflict, the relieving of neurotic symptoms, the promoting of further development in the mental apparatus, and the learning of more adequate social responses and modes of coping with stressful stimuli (Kessler 1966).

Personality disorders. The personality disorders differ from psychoneurotic disorders in children in the following ways. In personality disorders, chronic (fixed) pathological trends and traits are prominent, and they are ego-syntonic—that is, they are not perceived by the child as anxiety-arousing or as a source of distress. Most of the personality disorders in children appear to involve strong fixations and/or disturbances in earlier psychological and psychosexual development, related to crises and conflicts involving wishes for dependency and autonomy, the handling of sexual and aggressive impulses and behaviors, and sex role identification. The types of personality disorder which have been defined (Committee on Child Psychiatry 1965) include the anxious personality, compulsive personality, hysterical personality, overly dependent personality, oppositional personality, overly inhibited personality, overly independent personality, isolated personality, distrustful personality, personality with discharge disorder (impulse-ridden or neurotic types), and sociosyntonic personality disorder.

Discharge disorders. The discharge-disorder category includes many children who are classified in other systems as delinquent, acting-out, psychopathic, or sociopathic. Children in this general

category tend to act out directly their feelings and impulses in an antisocial and often highly destructive manner. Two subcategories have been defined which distinguish between an impulse-ridden group and a group in whose discharge disorder neurotic conflict plays an important role. There is a central tendency in both of these subgroups to discharge rather than delay or inhibit antisocial impulses, but the sources of the tendency to discharge differ. The child with an impulse-ridden personality shows low frustration tolerance and difficulty in controlling or channeling sexual and aggressive impulses; his interpersonal relationships tend to be shallow, he experiences little anxiety or guilt, and there is considerable deficiency in conscience development and in the development of flexible and complex defense mechanisms. He tends to have a history of extreme emotional deprivation. The neurotic personality disorder subgroup, on the other hand, has achieved a more complex level of personality development. The child in this subgroup has developed the capacity to internalize conflict, and his antisocial behavior tends to be reactive to such conflicts and to have unconscious symbolic significance to such conflicts. These children experience some anxiety and guilt, and their interpersonal relationships, while ambivalent, are warmer and more meaningful than those of children with impulse-ridden personality [see DELINQUENCY, article on PSYCHOLOGICAL ASPECTS; PSYCHOPATHIC PERSONALITY].

Developmental deviations. It is important to distinguish between the diagnoses of psychoneurosis and personality disorder, and *developmental deviations*. Some behaviors (for example, sexual deviations), often part of a neurotic and personality disorder, may also be related primarily to delay, acceleration, or unevenness in development and should be classified as developmental deviations rather than as neuroses or personality disorders.

Psychotic disorders. Psychotic mental disorders in children are characterized by marked and pervasive deviations from mental functioning normal for the child's age. In general, these disorders usually include chronic and severe impairment or deterioration of emotional relationships, preoccupation with inanimate objects, failure to develop speech or loss of speech for purposes of communication, bizarre behavior and unusual motility patterns, extreme mood swings and intensity of affective experience and expression (as in sudden temper outbursts, panic, etc.), and failure to develop or loss of a sense of individual identity. There are generally severe disturbances in perceptual and cognitive development and functioning, but with

onset in later childhood certain areas of intellectual functioning and achievement may be adequate or better. Some of the symptoms seen in childhood psychosis—such as some of the disorders in thinking, affect, perception, motility, speech, object relations, and reality testing—represent efforts at restitution or compensation for the psychotic process.

Autism and symbiotic psychosis. Childhood psychoses do not tend to crystallize into as many varieties or subtypes as is the case with adult psychoses (Kessler 1966). Two major subtypes have been defined in early childhood: infantile autism and symbiotic or interactional psychotic disorder. Age of onset in infantile autism is the first few months of life as the infant fails to develop a normal emotional attachment to a mother figure. He remains emotionally aloof, speech development is delayed or absent, feeding and sleeping problems and stereotyped motor and motility patterns are prominent, and the child responds to relatively slight changes in his environment with intense outbursts of anger or anxiety. Some intellectual functions are intact, but their use is impaired by the defective reality testing and lack of communication.

Age of onset of symbiotic psychosis is after the first year or two of life. The child develops a normal emotional attachment to his mother but fails to achieve separation and individuation. Intense and prolonged dependency upon the mother (or between mother and child) is prominent in the early history. The disorder is usually precipitated by some real or fantasied threat to the mother-child relationship. Symptoms include marked and severe separation anxiety, clinging (sometimes indiscriminately), regression (for example, giving up speech, loss of bowel control), gradual withdrawal from object relations, autistic behavior, and distortions in perceptual and cognitive functioning.

Childhood schizophrenia Childhood schizophrenia or "schizophreniform" psychotic disorder occurs in middle childhood—ages 6 through 12 or 13. The disorder may be of gradual or relatively acute onset. Where onset of the disorder is gradual, the development of neurotic symptoms is followed by regression to use of the primitive defenses of marked denial and projection. Low frustration tolerance, hypochondriacal tendencies, and inappropriate outbursts of temper or panic are often observed, and these are followed by withdrawal, increasing involvement in private fantasy, emotional aloofness, disorders in thinking and perception, autistic behavior, and a breakdown in reality testing (e.g., Goldfarb 1961). The prognosis is more

favorable if the psychosis is an acute reaction to a developmental crisis. Few adultlike hallucinations are experienced by psychotic children until ages 9 or 10 at least. However, bizarre motor behavior (for example, whirling), self-mutilation and suicidal attempts, and inappropriate mood swings are seen with some frequency in these cases. Occasionally, some of the symptoms more characteristic of adult psychoses are seen in children. These include ideas of reference, somatic delusions, catatonic behavior, and paranoia. [See SCHIZOPHRENIA.]

Parent-child relations. In diagnosing neurosis, personality disorder, or psychosis in children, the healthy, positive responses and capacities as well as psychopathological trends should be assessed, along with the positive and negative physical, social, and psychological determinants of the child's behavior (A. Freud 1965).

Current views of the diagnosis and treatment of mental disorders in children stress the importance of parent-child relationships, family processes, and sociocultural influences, while remaining cognizant of contributing and predisposing genetic and constitutional factors.

Disturbances in parent-child relationships have been implicated in a variety of children's mental disorders, including unusual fluctuations in mood, psychoneuroses, certain psychotic disorders, and "antisocial" personality disorders, as well as disorders in which both physical and psychological functions are disturbed, such as marasmus or failure to thrive in infants, ulcerative colitis, asthma, and disturbances in perceptual, cognitive, and sensory-motor functions related to structural changes in the central nervous system.

The connection between type of mental disorder and specific characteristics of parent-child relationships is complex and not clearly understood. Research on certain personality factors characteristic of parents of psychotic and neurotic children (such as that of Sarason et al. 1960) shows that parents of children with high anxiety differ in certain personality traits from parents of children with low anxiety, and the "superego lacunae" shown by Johnson and Szurek (1952) in the parents of some kinds of antisocial children indicate the probability of some specificity in the relationship between parent-child interaction variables and type and severity of mental disorder.

In addition to the quality of the parent-child relationship, other family variables may predispose and contribute to the development of mental disorders in children (e.g., Ross 1964). For example, loss of a family member, lack of family cohesive-

ness, distorted and neurotic communication patterns, deviant role functions, conflicting value orientations, or poor integration with the community may serve as stressful stimuli which upset the functioning of the family and lead to a reactive disorder, developmental deviation, neuroses, personality disorder, or psychoses in the child.

One of the characteristics of the healthy family is the capacity to respond adaptively to crisis. Serious illness, economic losses, death of a parent, removal to a new community, and other such stressful events tend to be disruptive of family equilibrium and established modes of functioning and relating. Such disruptions may be temporary and through mastery lead to a higher level of functioning, or they may continue and result in family disintegration or pathology in one or more family members.

There is some indication of a specific relationship between type of family disruption and type of mental disorder in the child. For example, certain types of delinquent acting-out tend to occur in families with little cohesiveness and faulty disciplinary practices (e.g., Bandura & Walters 1959; McCord et al. 1961). Certain patterns seem characteristic in families of children suffering from schizophrenia or certain types of autism (e.g., Lidz & Fleck 1960). However, as is the case with other variables which have been implicated to some degree in mental disorders of children, the establishment of clear-cut relations between family variables and individual child disorders depends upon further research.

Sociocultural variables have also been implicated in the etiology of children's mental disorders. Variations in child-rearing practices and attitudes have been noted in different ethnic and social-class groups and cultures, as have incidence and type of disorder and attitudes and responses to treatment (e.g., Whiting 1963; Clinard 1957). However, the social and psychological mechanisms mediating the relationship between sociocultural variables and mental disorder are still poorly understood. Potentially stressful events for families and individuals include movement from rural to urban areas; shifts in socioeconomic conditions and traditional customs, attitudes, and interpersonal functions; and the acculturation of primitive or previously relatively isolated cultures. Children who experience such events without adequate preparation are particularly vulnerable to mental disorder (Kessler 1966).

The economic, religious, and educational status of the family also seems related to the manner in

which the other family members react to mental disorder in a child, just as stereotypes of these groups tend to affect the treatment plans and services offered by agencies and clinicians.

VI

EXPERIMENTAL STUDY

Mental disorders vastly extend the normal range and variety of human behavior available for psychological study. They present familiar patterns in exaggerated form or in unusual combinations, incompletely developed, or disorganized. Although these derangements are often accompanied by seemingly arbitrary and unique manifestations, there is enough regularity in them to allow for prediction from one occasion to another and for generalization within groups of persons. Experiments help to determine lawful relations in this area, as they do in other fields.

Since mental derangements are often accompanied by considerable discomfort or distress, they call first for caretaking and administrative action which, if feasible, includes treatment and rehabilitation. In addition, mental disorders provide a source of information about the mechanisms of normal, as well as impaired, function. We are apt to take for granted our ability to execute the many intricate operations necessary for the coordinated and complete performance of even quite simple movements and mental processes. Only when these operations break down, become inefficient, or fail to develop do we recognize the contribution of one or another mechanism to normal functioning. Any

systematic examination of mental disorders involves the identification of the mechanisms or processes that are damaged in function. From this follows the determination of their part, typically in interaction with other mechanisms or processes, in the behavior disorder or symptoms. Such an analysis, often performed implicitly and schematically, constitutes the diagnosis. When it is explicit and precise, when it allows for prediction (i.e., prognosis) and is followed up by observations on the patient's progress, it can contribute to knowledge of mental function in general, as well as of psychopathology in particular.

Experimental techniques are better suited to the study of disorders in cognitive and motor function than to the study of disorders in emotions, but, with some ingenuity, these techniques have been made to serve in the exploration of affective and motivational anomalies as well. Experiments can serve to test a specific hypothesis or merely to verify the fact that some type of behavior does occur. More particularly, they are employed to determine the conditions under which such behavior occurs and the factors that influence its magnitude or frequency. Experimental techniques have been used not only to explore phenomena relevant to mental disorders but also to bring about such derangements (by drugs, fatigue, etc.) and to treat others that have emerged in the course of development or as a result of accident.

Thus, experimentation is appropriate at every stage of the evolution and remission of mental disorders. Its special virtue lies in its capacity to refine clinical observations, to evaluate their accuracy and delineate the boundaries of their validity, and to sort out the several sources that contribute to the effects under investigation. An experiment may be necessary, for example in diagnosis, to decide whether a patient's sensory or motor function has been completely lost or is available in extreme emergencies, as happens with hysterical conversion symptoms. Experimental procedures are also widely used to determine the extent of an incapacity. These may include procedures such as perimetry of visual fields and determination of dark adaptation, or performance tasks, such as memorizing pairs of nonsense words and sorting designs.

Psychological tests used in diagnosis also have their origin in experimental procedure and retain some of its features—the objective tests more so than the projective. For example, certain aspects of the test situation are always standardized, e.g., the content and phrasing of the questions, the instructions given, the perceptual information presented, the method of recording the patient's re-

sponses, the format of the protocol taken for the record. In other respects clinical tests may not satisfy the requirements of control and reproducibility that distinguish the experimental from other methods of observation. Also, clinical test scores are evaluated against pre-established population norms, an advantage over the experimental method in determining the baseline and the extent of the deviation, that may have significance for psychopathology. In standardized tests, however, a significant clue could be missed if it emerges, not against the background of average performance, but in the unique pattern of the particular patient's function and dysfunction. Here the flexibility of the experimental method, its resources of manipulation and control, and, above all, its rationale of specifying functions by operations offer the investigator a considerable gain. [See PERSONALITY MEASUREMENT; PROJECTIVE METHODS.]

Although this article is concerned with the *psychological* study of mental disorders, it should be remembered that these disorders furnish subjects for experimental investigation by other disciplines, e.g., pathology, biochemistry, and neurophysiology. Even within psychology, the spectrum of experimental techniques and problem areas covers a wide range, from physiology to the social sciences. Experiments in autonomic and endocrine function, for instance, belong within its boundaries and have been of especial interest to students of unconscious psychic processes. At the other end, experiments in role playing, in group processes, and in the restructuring of social systems, such as hospital wards, have been undertaken jointly or alternately by psychologists and social scientists. The middle ground is marked by experiments in psychophysical measurement and perceptual judgment, by the several conditioning techniques, and by the immense variety of performance tasks—from simple motor responses to the solution of syllogistic problems, from the retention of nonsense syllables over a few minutes to the enduring acquisition of a new skill. [See PSYCHIATRY, *article on* SOCIAL PSYCHIATRY.]

As in other areas of research, in the study of mental disorders the experimental approach implies that as many as possible of the conditions that bear upon the subject under investigation are held constant, while the others are controlled by the design of the research. Only a few, and preferably only one, of the conditions is allowed to vary, and that one is varied systematically, so that its effect on the outcome can be evaluated, whenever possible in some quantified terms. The purpose of an experiment is not just to discover whether an

anticipated result can be discerned but also to give an estimate of its magnitude and of the probability that it could be reproduced under similar circumstances.

In this methodological sense, "experiment" means something very different from the improvised trial or casual exploration to which the name is also applied. Ventures of that type are not unknown in the study of mental disorders, especially in the study of treatment and rehabilitation programs. They may be successful and even valuable in suggesting hypotheses or in demolishing an established misconception, but they are not experiments in the sense that their results can be attributed to a specific variable in the total situation. Certain guesses at the hidden meaning of a patient's obscure statement are experimental in this improvisational sense. Even though they may solve a riddle, there is no certainty that they hold the only solution or, indeed, that the riddle has been posed. Like other intuitive observations, such stabs at interpretation or intervention can supply hypotheses for subsequent testing.

Historical aspect. The experimental method was introduced into the study of mental disorders soon after it appeared in general psychology. Kraepelin, the great system builder in clinical psychiatry, had worked with Wundt, and in due course he founded an experimental psychological laboratory at his research institute in Munich. Its program was outlined as far back as 1894, while Kraepelin was in Heidelberg, and appeared in print as the first in a series of reports under the title *Psychologische Arbeiten* (Kraepelin 1896). Periodic publications on research conducted by Kraepelin himself, and, under Kraepelin's editorship, on work done by his associates and students, followed during the first quarter of the twentieth century and constitute a record of eight volumes [see KRAEPELIN]. Kraepelin credited Gabriele Buccola, an Italian, with the first psychophysical experiments on patients with mental disorders and also noted the beginnings of such research in Russia and the United States. Another neuropsychiatrist whose prolific experimental activity started before the turn of the century was Paul Ranschburg, a Hungarian, most noted for his research in memory disturbances. By 1902 Ranschburg had established a permanent laboratory in Budapest, with government support, for the study of abnormal mental function.

In America, Shepard Ivory Franz set up the first laboratory dedicated to the experimental study of behavior in mental patients, at the McLean Hospital in Belmont, Massachusetts, in 1904. The apparatus came from Leipzig, and Franz's first ex-

periments were concerned with the association areas in the brain, aphasia, memory defects, and especially with the physiology of manic-depressive psychosis. Psychological research was typically introduced into mental hospitals via physiology, with experiments on fatigue, speed of reaction, and time judgment. Significantly, Franz's laboratory was established for research in *pathological physiology*. When in 1907 he transferred his activities to the Government Hospital for the Insane in Washington, D.C., F. L. Wells succeeded him at McLean, heading a laboratory in *pathological psychology*. Wells was indeed less interested than Franz in cerebral localization, and his work in clinical psychology is best remembered for experiments in reaction time, the design of psychometric tests, and the pioneer use of psychogalvanic measurement.

Kraepelin's experimental program encompassed all the principal approaches to mental disorders. He studied normal function, in order to establish baselines, isolate distinct mental processes, and perfect techniques for their measurement. The same processes were also investigated in patients with various mental diseases and with mental disturbances brought on by drugs, fatigue, or sleep deprivation. The ultimate goal was to gain a clearer understanding of mental illness in order to determine its etiology and render its treatment more effective and more amenable to evaluation. Kraepelin's methodological goals have proved understandably uncongenial to the currently dominant school of psychiatry. One clue to his unpopularity is his definition of psychology as a branch of physiology, i.e., physiology of the mind. It is a definition that today few, even among his admirers, would accept, although the concepts underlying it inspired his research. The definition implied that mental function can be measured, that deranged mental function differs from the normal in some quantifiable properties; that operations allowing for the exact assessment of the speed, the regularity, or the frequency of certain incidents in performance can serve as diagnostic and prognostic devices.

This view entailed neither an atomistic model of personality nor a denial of psychogenic etiology. Kraepelin unequivocally declared that the physician concerned with mental disorders aims at forming a total picture of his patient and that the vast majority of these disorders originate from inside—genetic disposition being one of the prime determining factors. Experimental psychologists of the present day, while paying homage to his pioneer work, nonetheless adopt a critical attitude toward Kraepelin's contribution, for two reasons. One is the structuralist theory he inherited from Wundt.

which has proved to be of limited value—especially Wundt's concept of apperception, which played an important part in the theory of Kraepelin's school. Second, Kraepelin himself and several of his associates—although not all, Ernst Grünthal being a notable exception—worked with extremely small samples of subjects. Typically, the investigator himself, not only dubiously representative of the general population but also far from naive in regard to the anticipated effects of the experimental treatment, was the only subject. Kraepelin and an associate's report of impaired performance attributed to a daily dose of alcohol no larger than two quarts of beer is the envy of later experimentalists who, like the author, have been unsuccessful in demonstrating impairment with much larger doses of alcohol [see DRINKING AND ALCOHOLISM, article on PSYCHOLOGICAL ASPECTS].

Theory and operationalism. While the program expounded by Kraepelin has been adapted by experimentalists to other psychological theories and to the requirements of representative sampling and stricter control, laboratory research on problems related to mental disorders has branched in other directions as well. Hughlings Jackson's hierarchic model of dissolution of function (1884) has stimulated innumerable experiments, especially with neurological patients, and Pavlov's theory of conditioning has been applied to mental disorders of every kind. Whether tied to a theoretical position or concerned only with the problem in hand, experimental studies of neurological patients have enriched, refined, and at times corrected our notions about sensory and motor function and higher mental processes. Since the purpose of most investigators has been to isolate the damaged function from those that remain intact or to arrive at a differential determination of deficit, the general approach to neurological disorders has been operational. The experimenter defines the function that seems impaired, selects operations that involve the function, and sets the patient experimental tasks that test these operations.

As a rule, the more closely defined these operations, the more informative they are to the investigator. This scale of value may, however, be reversed by his commitment to a theory couched in such global constructs that each and any derangement in function serves as an illustration of the general principle. A classical instance of that view, advanced by a clinician who was also a notable experimenter, is Goldstein's principle of abstraction. Goldstein conceived of abstraction as a composite function, central to which is the ability to categorize concrete instances. Its impairment is cited to ac-

count for disorders in speech and in thought, for the psychopathology associated with lesions in diverse areas of the brain, and for disorders that occur without known cerebral damage, such as schizophrenia. [See GOLDSTEIN.]

Werner's developmental principle was another such general concept, which inspired experimental attacks on mental derangements as diverse as aphasia, the psychoses, and mental deficiency. Implicit in Werner's principle is the notion that seemingly instantaneous events in perception and thought in fact evolve by steps over a microscopic time scale. The evolution of these processes is usually too rapid to be open to inspection, but with appropriate experimental techniques it can be demonstrated in some instances of disturbed mental function. This was done, for example, by Klaus Conrad, a clinical psychiatrist and ingenious experimenter, who derived quite specific neuropsychological formulations from the broad and formal gestalt laws of integration and differentiation.

In the aphasias, amnesias, and other cognitive derangements, experiments with the tachistoscope and memory drum (laboratory instruments for the regular, and very short, presentation of visual displays) merely extended the routine neurological examination and psychological testing. Students of the psychoses and psychoneuroses, on the other hand, could not always admit the relevance of experimental techniques. The psychoanalytic school, which in one version or another has undoubtedly been the most influential force in psychiatry and its ancillary professions in the United States, relies on analogy rather than on operational constructs. This applies even more emphatically to the existentialist and other metaphysical doctrines of psychiatry. In these theories explanation is more often by retrodiction than by prediction; the antecedent events are reconstructed without an exact weighting of the factors that contributed to the outcome or an analysis of their interaction. [See PSYCHOLOGY, article on EXISTENTIAL PSYCHOLOGY.]

Animal research. To be sure, certain key concepts in psychoanalytic theory, such as conflict, have been subjected to laboratory experiments. The effects of stress interviews, frustration, pain, and vexation have been studied with human subjects, but for obvious reasons the threat to health and human dignity had to be well below the level at which lasting mental disorders are likely to develop. Most of the laboratory studies, therefore, have been done with infrahuman species. A powerful stimulus to such studies was the almost undivided sway of learning theory in American experimental psychology following the behaviorist

revolution. If mental disorders, or so many of them, are not diseases but, rather, clusters of maladaptive habits and drives, persistently faulty perceptions or thoughts, and stunted social skills, then the laws of learning and conditioning may explain the emergence of symptoms and lead to successful methods of treatment. Attempts to reconcile the clinical formulations of Freud with an experimentally based academic theory appealed strongly to Hull and his school, whose learning theory shared with psychoanalysis a hedonic principle of motivation. It is, perhaps, disappointing that experiments concerning the development of defense mechanisms have been largely equivocal (see Sears 1943; Miller 1944), although this is hardly surprising in view of the fact that most of them employed rats for subjects. [See CONFLICT, article on PSYCHOLOGICAL ASPECTS; LEARNING THEORY; STRESS; and the biography of HULL.]

While there is unquestionable elegance in the graphic representation of gradients and the equilibrium point between a rat's approach to food and avoidance of shock and there is quite live evidence of regression, fixation, and other maladaptive habits in the experimentally induced neuroses of cats, dogs, pigs, and sheep trapped in a physical or psychological harness (Liddell 1944), the leap from the laboratory to the human family setting is still a long one. It has been quite spectacularly shortened by Harlow's experiments with monkeys (1958; 1962). The affectionate display directed by infant monkeys toward their surrogate mothers—cloth dummies—was not only comparable with their responses to the natural mothers but also uncannily reminiscent of the behavior of human infants. Since these observations were made in a laboratory, several influences on the growth of affectional responses could be controlled and systematically varied. Furthermore, the situation seemed more likely to produce a lasting mental disturbance similar to those that afflict man than did the traditional procedure of inducing experimental neurosis in social isolation. As the monkeys grew up, some of them indeed developed marked personality disorders. Rather surprisingly, however, this outcome could not be traced to the artificial surroundings of the laboratory or to the substitution of a cloth dummy for the mother or, indeed, to her replacement by surrogates who rejected the clinging infant with a violent mechanical thrust or a concentrated blast of air. The infant experience that seemed chiefly to account for the adult monkey's psychopathology was deprivation of contact with other infants. [See AFFECTION; INFANCY.]

Mental disorders and brain function. The problems of generalizing from infrahuman animals to man will be briefly considered below. At this juncture another problem demands attention: the relationship of mental disorders to disturbed brain function. The conception that behavior disorders develop as a result of infantile deprivation or other stressful life experiences makes no explicit assumptions about alterations in the organism by which such effects could be mediated over time. It is, of course, tacitly assumed that learning, whether it results in greater efficiency or is maladaptive, involves some enduring organic changes, more particularly in the central nervous system. What these changes are is unknown, partly because of the inadequacy of current neurological techniques and partly because of the inadequacy of neuropsychological concepts. These two factors are as closely related as are technology and theory in other domains.

After many false attributions and an occasional correct guess in past centuries, it is now pretty universally agreed that the organ of the mind is the brain. The traditional metaphysical controversies about the relationship of body and mind have not been so completely resolved. They may be dismissed as irrelevant to the problem of mental disorders, but there survives a prejudice from the days when body and mind were regarded as two distinct substances, coordinate but not coequal in value or power. In the chain of being, man occupied a position intermediate between that of inanimate matter and the soulless animals, with whom he shared the bodily attributes, and that of the several classes of spiritual beings, whom he resembled by virtue of his mental faculties. His mind received credit for very extensive powers over the body, while control in the reverse direction was thought to be more limited in scope and also to be a likely avenue to sin. Moral judgments have changed but clinicians are still apt to regard brain damage as but one of several causes of mental disorder and quite readily attribute disturbances in visible and tangible behavior to psychic processes that, at least by implication, take place outside the bodily dimensions.

The implication is made by the rough division between organic and functional disorders that has been established in the usage of psychiatrists and neurologists, as well as of clinical psychologists. "Organic" refers to brain damage, and that term is understood to stand for such structural impairment of brain tissue as can be observed directly or by means of currently available neurological tech-

niques, e.g., electroencephalography, pneumography, angiography, etc. "Functional," by elimination, does not refer to organic or brain function. A classificatory principle as incompatible with present-day scientific notions as this is can be defended only on pragmatic grounds. It may, indeed, help with the prescription of treatment, but it introduces an unnecessary division into the research on mental disorders.

Localization of brain function. On the one hand, investigations of patients with brain lesions tend to be focused exclusively on the topographical localization of the damaged function. Preoccupation with specialized centers or areas discourages the search for functional systems in the brain or, for that matter, in behavior and experience. On the other hand, psychological concepts have been derived without reference to systems and processes within the organism, and it is hardly astonishing that they do not always fit exactly the neurologist's model. Derangement of function, especially when it can be determined independently by neurological techniques and by experimental studies of behavior, furnishes the most revealing clues about mechanisms and systems common to neurology and psychology. The concepts and patterns that will be meaningful in both disciplines need not correspond to those presently current in either. For example, if future research confirms the author's experimental and clinical observations about the close association of an extremely severe memory disorder with a general lack of spontaneity in the patient's behavior—although no comparable deficit in reasoning or intelligence is found—these two seemingly unrelated psychological functions could be properly subsumed under a common concept. Moreover, if evidence accumulates that this combined deficit occurs with lesions in a certain fairly well defined subcortical system of the brain, such a concept should be meaningful in the language of neural as well as of behavioral processes.

Although the accomplishment of experimental studies aimed at this objective is but modest to date, the advance has been considerable (a good share of that achievement being the result of investigations of disordered mental function; see Boring 1929; Flugel 1933; Hebb 1949; 1958) since G. Spurzheim, who ranks next to Franz Joseph Gall as the founder of phrenology, drew his spuriously detailed map of some thirty-odd brain areas that subserved as many mental faculties, with mirrorlike duplication in the two hemispheres. More reliable evidence for the functional subdivision of the brain came first from Paul Broca's clinical

observations and shortly afterward from Luigi Rolando's experiments with electrical stimulation. Pierre Flourens, another pioneer in experimental research in this area, however, arrived at different conclusions in his studies using the extirpation technique. Phrenology survives today in the mosaic theory of the brain. An opposite point of view was forcefully advanced by Goldstein, whose concept of abstraction has already been mentioned, and, for a while, by Lashley, who derived the laws of mass action and equipotentiality from ablation experiments. These laws imply that the size, rather than the site, of brain damage determines the disturbance in behavior and that—outside the sensory and motor areas—any part of the cortex can potentially subserve any learned behavior. [See Broca; FLOURENS; GALL; LASHLEY.]

Laboratory studies of human patients have led to formulations intermediate between the two poles. Teuber, who conducted extensive and carefully designed experiments on a group of patients with combat injuries, the majority with gunshot wounds in the brain, demonstrated that these lesions result in both specific and general impairment of perceptual function (Teuber & Liebert 1958). Halstead reached a somewhat different, intermediate position, from studies of patients with lesions in the various lobes of the cortex (1947). Statistical analysis of his experimental results showed that no intellectual function is uniquely dependent on a single region of the brain but that these areas differ in their importance for one or another function.

Experimental techniques have been extensively used to test hypotheses about cerebral dominance and the division of function between the hemispheres. In this context one again meets spokesmen of extreme as well as intermediate positions. At one pole is the opinion that man has two brains, that one hemisphere all but completely duplicates the function of the other. Indeed, experiments have repeatedly shown that the surgical removal of a diseased hemisphere or its decay through atrophy may cause little discernible loss of intellectual ability. Opponents of this view attribute a high degree of specialization to each half. Speech, for example, has been associated with the left hemisphere since Broca's time, and, correspondingly, control over manipulative skills has been attributed to the right hemisphere. The proposition that cerebral dominance is thus manifested and that it is reversed in left-handed persons has been tested by many experimenters. Zangwill's survey (1960) of these studies reached the conclusion that the speech area is not invariably contralateral to the dominant

hand. Nor is representation exactly identical in the two hemispheres when (as, for example, in sensory function) the rule of contralaterality obtains. Semmes and her associates (1960) have demonstrated this for somatosensory function, while experiments determining the two-point discrimination and pressure thresholds were used in Teuber's study of disabled veterans (Teuber & Liebert 1958).

Pathological damage to the brain that corresponds exactly to a functional impairment is the exception and so far has not been found typical of mental disorders. Lesions in the visual or auditory cortex offer the closest examples. Students of mental illness have been especially interested in the frontal lobe, which seems to play an important part in such emotional disturbances as depression and distress over pain. A functional severance of the prefrontal cortex from the central nervous system has been successfully applied in treating these complaints. Experimental studies, however, have been inconclusive in assigning a particular function or ability to the frontal lobe. Advocates of the mosaic theory of brain function have found more encouragement in the temporal lobe. Penfield, the neurosurgeon, exposed the temporal cortex in several patients while removing a focus of epileptic discharge (1954). Applying electric stimulation to clearly marked points, he was able to elicit repeatedly—although not always—the same sensation or evoke recall of the identical episode from the past. These recollections appeared to be as sensorially sharp as the original experience, even though the patient was fully aware of his immediate surroundings in the operating room. At first it seemed that the site where the organism stores its discrete memories had been discovered in the temporal lobe, and although later interpretations have been more cautious, they do not diminish the significance of these experimental findings, especially for the demonstration that experiences and memories are classified in the nervous system according to abstract principles.

This deeply hidden surface of the cortex and the adjacent subcortical regions are undoubtedly implicated in some of the processes of memory. Milner's reports with Penfield (Milner & Penfield 1955) and with Scoville (Scoville & Milner 1957), as well as other investigators' reports on patients who had lesions from surgery or disease in those areas, have noted grave defects in memory for recent events. Memory for remote events—like those which emerged under stimulation of the temporal cortex—is less consistently and less severely affected. Newer techniques in brain surgery, such as electro-

coagulation, have widened the area of experimental investigation of neuropsychological processes. Experiments performed with chronically implanted electrodes allow for the simultaneous recording of neuroelectric activity at deep brain centers and of overt behavior, as well as for electric stimulation. The subject in such investigations, however, is always a sick person, whose function is often influenced by drugs as well as the disease. Alternatively, the subject of an investigation may be a healthy monkey or cat, animals whose brains as well as behavioral repertoire have a good deal in common with man, although not quite as much as would satisfy many students of mental disorders. [See NERVOUS SYSTEM, article on BRAIN STIMULATION.]

Clinical research. There are well-established anatomical differences between the brain of man and that of even the highest subhuman primate; there is also reason to believe that some structures or neurophysiological systems are identical but serve different functions at the two different phylogenetic levels. Whether the accomplishments of the rat or the ape in learning and problem solving furnish an informative analogy for man's feats in forming unique memories and operating with symbols remains a debatable issue. Many experiments tracing the relationships between derangements in behavior and in the brain can be carried out only with human patients, because the psychological defect is entirely in the use of language. The variety of aphasia distinguished in clinical observation and confirmed by experimental tests are proof not so much of an ingenuity in classificatory exercises as of the scientific endeavor to expand our knowledge of significant lawful relationships. [See LANGUAGE, article on SPEECH PATHOLOGY; PERCEPTION, article on SPEECH PERCEPTION.]

Kinsbourne and Warrington's investigation of six patients with a reading disability (1962) is an example of the contribution experimental procedures can make in a clinical situation. These patients were right-handed, and they were known to have brain lesions in the right (i.e., minor) hemisphere. Paralexia errors, which their defects first seemed to exemplify, are regarded as aphasic in origin and are therefore attributed to damage in the dominant hemisphere. It appeared significant that the errors observed in these patients also differed from those commonly made in reading, in that they tended to occur with the first letters of a word. The investigators designed experiments to test the hypothesis that the reading errors arose from a perceptual derangement. By means of a

tachistoscope, they exposed to the patients brief glimpses of whole and fragmented words and geometrical figures. It became apparent that the patients had an abnormal field of perception, in which fine discriminations were restricted to the right side, although gross operations, such as judging the length of words, were unaffected. Unaware of their disability, the patients attempted to complete what they could read of a word, always in a leftward direction. Experimental checks ruled out the possibility that the disability arose from faulty fixation or defective eye movements, and the investigators therefore attributed it to an abnormal distribution of visual attention—to an unconscious neglect of space. They also recognized that their findings may have implications for reading disabilities that originate from a failure to execute the normal operation of forward completion. [See READING DISABILITIES; VISION, *article on EYE MOVEMENTS*.]

Multidisciplinary contributions. Experiments following the trail between mental disturbances and cerebral dysfunction, in either direction, have the advantage of a clearly defined objective. The pursuit itself, however, may become exceedingly complex and involve—over and above the neurological and psychological considerations—such diverse disciplines as biochemistry, genetics, social science, and history (the patient's life history, as well as the history of the disease process). These disciplines have indeed appeared more promising for research in schizophrenia than have the neural sciences. Experimental studies of schizophrenia in the biochemistry laboratory, although varied, allow for a broad, threefold classification. Their goal is (1) to determine the chemical causes of the mental disorder; or (2) to assess metabolic, and particularly endocrine, function in patients, at different stages of their illness, under induced stress, special experimental conditions, or in the standard hospital setting; or (3) to form a part of a pharmacological treatment program. These experiments often include investigations of physiological and/or psychological function as well.

Experimental studies of schizophrenia, manic-depressive psychosis, and the neuroses are typically confined to the verification of clinical observations. The major exception to this trend has been research stimulated by theories that do not distinguish between functional disturbances attributed to brain damage and those due to psychological factors. Followers of Hughlings Jackson and Head, of Pavlov and the gestalt school, of Goldstein, Werner, and Schilder, have exerted an influence in that

direction. More recently, models built around the activating properties of a subcortical neural system have served as a comprehensive conceptual framework for disordered mental function.

Theories that transcend the boundaries of established brain damage and psychogenic dysfunction employ loose and not fully operational constructs. Goldstein's principle of abstraction is an example, and, indeed, several experimenters have produced partial evidence against it. Some of these support Cameron's proposition (1947) that distractibility is an important source of concrete thinking in schizophrenia and that in several instances of mental disorder abstraction is manifested but is masked by the use of inappropriate, overinclusive, bizarre concepts, especially when they concern the social context. Of course, the conclusions of these experiments are limited by the extent to which their operations represent abstractness and concreteness in thinking. Uncertainty and disagreement about adequate correspondence between behavior under laboratory control and hypothetical mechanisms or processes—in personality dynamics or neural function alike—present the most difficult problem to the experimental psychologist investigating mental disorders.

Laboratory techniques. Experimental reports about the slow responses, sluggish work rate, and straying attention of depressed or schizophrenic patients are unlikely to arouse much controversy. In these instances, behavior observed in the laboratory does not conflict with clinical impressions, although inferences drawn from the two sets of data to underlying mechanisms may clash, whether they concern hypothetical psychic mechanisms, such as defenses against impulses, or hypothetical neural mechanisms, such as cortical arousal. Experimental techniques have also been used as a subsidiary procedure to clinical interviewing, e.g., the measuring of motor and autonomic responses in tests of word association or perception. If a patient seems to be unusually disturbed or ill at ease when discussing—or keeping silent about—certain topics, such suggestive impressions can be confirmed by the relatively exact measurement of his psychogalvanic response or hand movements. Evidence thus obtained may help in delineating and exploring his areas of conflict. This technique—popularly known as the lie detector—was systematically explored for the purpose of psychological research by Luriiia in Moscow in the 1920s (1932). Other investigators, in the United States as well as in the Soviet Union, have further developed this technique, following clues from the patient's auto-

onomic and skeletal behavior and measuring the latency, rhythm, and amplitude of his responses in structured interviews or during his performance of an experimental task.

Laboratory techniques have also been used in the study of the regularity of grossly distorted perceptions in patients with mental disorders. Estimates of the patient's body or of its parts; of the size and distance of objects, especially when the judgment involves the perceptual constancies; and of his dependence on external cues for accurate assessment of the vertical dimension have added to our knowledge of the effects of mental disease or of particular diagnostic types, but have neither promised nor succeeded in getting at the roots of these disorders.

Malmo and his associates (1951) have questioned the wisdom of resorting to tests of perception, and especially of concept formation, in order to establish characteristic differences between normal persons and neurotic or psychotic patients. In an experiment demanding difficult perceptual judgment under time pressure, it was demonstrated that groups representing these three classes barely differed in their accuracy. They did differ, though, in the regularity and duration of the motor response by which they indicated their judgment (this was simply pressing a button with the right thumb). They also differed in the frequency and magnitude of the synchronous response with the left hand and in the motor activity of their left hand between responses. The experimenters presented these results in support of the thesis that disproportionate motor disturbance is typical of patients with mental disorder under any stressful situation, and not only when the stress is specific to their emotional problem.

This line of reasoning is very congenial to Eysenck (1947; 1961), who has undertaken the most ambitious and extensive experimental research in mental disorders, with the purpose of establishing a reliable psychiatric nosology. Experimental studies have played an important part in this program and have contributed data to the factor analyses from which three personality dimensions were derived. One of these represents introversion-extroversion and accounts for certain individual differences in normal, healthy persons, as well as for the two types of disorders into which Eysenck groups the neuroses. The other dimensions represent the magnitude of a patient's neurotic and psychotic disturbance. The three dimensions are orthogonal to each other (i.e., independent), so that the extent of a patient's psychotic derangement is unrelated to the magnitude or type of his

neurotic abnormality. Most of Eysenck's earlier experiments demanded performance of some task, but more recently he has preferred laboratory methods that call for judgments on perceptual illusions or aftereffects. Some of these procedures, such as assessing the afterimage of a rotating spiral, have been widely used by clinical psychologists for diagnostic as well as research purposes.

Induction and treatment. Experimental techniques have also been used for the induction and treatment of mental disorders. While the development of a lasting experimental neurosis in an animal may be a perfectly justified venture, with human subjects the derangement of mental function can be considered only if it is a reversible process of short duration. Various psychotomimetic drugs have been used for this purpose, producing effects that have been reported as pleasant by some, disagreeable by others, and weird by most persons undergoing the experience. Perception and thought processes are distorted in fairly predictable fashion, but it remains a matter of debate whether the abnormal effects thus induced are the same as, similar to, or different in character from those of, for example, schizophrenia. Sleep deprivation, extreme fatigue, anoxia, starvation, heat and cold, excessive sensory stimulation (e.g., continuous noise) and its opposite, sensory and social isolation, have been among the experimental devices used to induce transitory mental disorders. [See **DRUGS; PERCEPTION, article on PERCEPTUAL DEPRIVATION.**]

The application of experimental techniques to the treatment of mental disorders has received its strongest impetus from theories of conditioning. The therapeutic goal is to retrain the patient by progressive weakening of the maladaptive habit or symptom or by reinforcement of an adaptive response. From isolated experiments with laboratory techniques to cure enuresis or hysterical tics or paralysis, or to reach autistic or mentally defective children, there has now developed a recognized practice of behavior therapy. Its methods—desensitization, satiation, counterconditioning, reciprocal inhibition, operant and avoidance conditioning—were formulated and first tested with animals. Now they are applied by clinicians, whose relationship to the patient may not be very different from the psychotherapist's. Also, like the latter, the behavior therapist can combine psychological treatment with pharmacological treatment. [See **LEARNING, articles on CLASSICAL CONDITIONING, INSTRUMENTAL LEARNING, and AVOIDANCE LEARNING; LEARNING THEORY; MENTAL DISORDERS, TREATMENT OF, article on BEHAVIOR THERAPY.**]

Drug therapy and electroshock treatment have

many of the features of a research experiment. The agents administered to bring about certain effects, i.e., improvement in the patient's condition, are under control. The amount given, the duration of treatment, and the avenue by which the agent is administered can be varied, within limits, and the manifestation of side effects, as well as of the principal outcome, can be evaluated and related to the input variables. Opportunities to explore these relationships have been thoroughly exploited by experimenters. [See ELECTROCONVULSIVE SHOCK; MENTAL DISORDERS, TREATMENT OF, article on SOMATIC TREATMENT.]

The use of experiments in evaluating process and outcome in psychotherapy is far more limited. In individual and group therapy alike, too many of the relevant influences are outside the scope of controlled manipulation. Hypnotherapy offers more attractive possibilities; indeed, all research related to hypnosis seems to be relevant to an understanding of mental derangements and, in the light of Orne's findings, to an accurate assessment of experimental findings in psychology. Orne's experiments (1959) have shown that behavior under hypnosis depends very largely on the current notions about hypnotic effects and, also, that subjects volunteering for psychological experiments tend to have very definite ideas about how they are expected to behave in the laboratory, ideas which may exert a considerable influence on what they do or accomplish there. [See HYPNOSIS.]

Experiments in human behavior, whether they reflect normal or disordered mental function, pose certain problems that are of little or no concern to experimenters in other biological sciences. The patient or control subject does not ever merely react to stimuli. The best the experimenter can achieve is to elicit, with his instructions and setting, an unprejudiced cooperation and to rely on observations that allow the least possible latitude for subjective interpretation. In the course of his work he may make new and significant clinical observations or discover lawful relationships that explain some phenomena of the mental disorders. His special contribution, however, is the testing of such observations and the definition of clinical terms by operations that are reproducible and open to inspection by all who will take the trouble to look.

PSYCHOLOGICAL TREATMENT

Within the context of this article, the term "psychological treatment" means psychotherapy and "mental disorder" means mental distress. Psychotherapy consists of a group of communicative methods for exchanging semantic information with the aim of relieving mental distress. Mental distress consists of behavior patterns subjectively experienced as painful and judged by subjective and objective observers to be inappropriate to a context.

Although there are now several psychotherapeutic approaches in Western culture, only a few can be considered as seriously developed alternatives whose methods continue to be evaluated and improved through systematic study. These approaches can be subdivided into three schools—psychoanalytic-psychodynamic, learning theory, and client-centered. Although many similarities and differences can be found among these schools, depending upon how one compares them, there is agreement regarding a number of essential components in mental distress and its treatment by psychotherapy (Ford & Urban 1963).

Modern psychotherapy was derived mainly from the efforts of Josef Breuer and Sigmund Freud, toward the end of the nineteenth century, to systematize a "talking cure" from the hypnotic techniques of the time. From this beginning several methods have evolved, none showing a clear-cut superiority over the others. They share many presuppositions regarding the nature of man and a delineation of individual psychotherapy as a private two-person relationship limited to talking and listening, the intent of which is to relieve the mental suffering of a patient in an enduring way. This private and intimate relationship, peculiar to Western man at this time, is notable as much for what it does not contain as for what it does. For example, it is a regularly repeated human communion that is unaccompanied by food and drink.

Presuppositions are vaguely held and seldom

examined beliefs. Beliefs concerning the nature of man underlie the articulated suppositions of psychotherapy. This *Menschanschauung*, as it might be called, presupposes that man's suffering is an outcome of his experience, that mental suffering should be relieved, that man has some degree of freedom of choice and decision, that he can control himself to some extent, that he can be changed by experience, that one man can help another to change, and so on. A complete inventory of such presuppositions has never been attempted, and perhaps because of the tacit nature of such beliefs, no inventory could be complete. It is of obvious importance that these beliefs are held by both therapist and patient.

The more clearly held beliefs of therapists make up the specifiable suppositions and assumptions of psychotherapy theory. A therapist operates with a theory of the pathology (Greek, *pathos*, suffering) of mental processes and a theory regarding techniques that can bring about beneficial change in them.

Here the term "theory" refers to a rough framework of notions expressed in a language containing everyday and special terms. A therapist's theories do not represent formal systematized bodies of tested and established hypotheses, such as those found in some natural sciences. This is not so much due to the youth of the field as to its nature. Therapy is not a science but a practical healing art. Practical arts consist of techniques for achieving ends valued as good. Procedures and rules for achieving ends can be aided by basic scientific knowledge that increases our understanding of the subject matter or augments the power of techniques. The effective utilization of techniques remains in the hands of a skilled artisan whose work represents the conduct of an artistic rather than a scientific activity.

Theories of mental distress

A therapist's theories begin with conceptual notions about the subject matter to which his techniques will be applied. Mental suffering involves a set of conditions judged to be qualitatively or quantitatively inappropriate to a context. This judgment is made both by an internal observer, a patient, and by an external observer, a therapist, both of whom hold beliefs about ideal or desirable types of behavior for various contexts. The judgments that something is out of order are arrived at not by consulting experimental or statistical evidence, but by comparison of the patient's behavior with ideal types. This comparative method uses a concept of desirable behavior that represents an idealization,

a useful fiction, and not the extreme of an observable range.

The chief empirical indications of mental distress, some or all of which are evident to both observers, are negative affects, thought distortions, and constrictions.

Common negative affects, subjectively experienced and reportable as intense and not in keeping with an external situation, are anxiety, anger, depression, shame, and guilt. For example, a person may experience great anxiety in a classroom where there is no evident threat. Or he may become repeatedly enraged at frustrations that he judges to be trivial. Or he may enter a prolonged depression over the death of a loved one and even feel, inexplicably, guilt over the loss.

Thought distortions have a great range of severity and variety of content. Common are beliefs that one is inferior, that one deserves admiration, that a disaster is about to occur, that one is being looked at or talked about, that people are dangerous, that one's body is defective, and that the opposite sex is hostile. These beliefs are often accompanied by the patient's own judgment that they are unwarranted or unjustified to this degree. Yet this judgment seems powerless to correct the thought distortion.

Constrictions involve limitations of feelings or behavior required by and congruent with contexts. These limitations include avoidance of the opposite sex, sexual impotence or frigidity, inability to enjoy life, and an incapacity to experience either joy or grief. Such constrictions have far-reaching consequences and lead to repetitions of old patterns in novel situations requiring discriminations and new behaviors.

There is great variation in how much distress an individual can stand. Most applicants for therapy have experienced enduring distress of more than mild severity which has not disappeared in the course of time. A patient seeks expert help for the negative affects, thought distortions, or constrictions that trouble him, and it is these phenomena from which a therapist attempts to release a patient by modifying the processes that generate them.

For more than five thousand years there have been attempts to classify symptoms, descriptions, and behavior patterns into disease categories (Menninger et al. 1963). All these efforts have failed to produce reliable categories. The growing modern view is that we are not dealing with disease entities in the medical sense but with states of experiencing that require conceptualizations different from those found in traditional medicine.

Today, various schools of psychotherapy have

reached moderate agreement on which elements are essential in descriptions of mental distress. Theories of the underlying pathological processes also agree insofar as they consider mental conflict, anxiety and other negative affect processes, and the ontogenesis of distress in parent-child relations to be crucial variables. The current uncertainty and disputes center on the problem of determining the best techniques for relieving distress and producing change. Although a crude theory of distress exists, we lack a theory both of mental change and of how change comes from external social influence. Hence there exists a profusion of techniques derived from clinical experience, but they lack a satisfactory theoretical underpinning.

Theories and techniques of therapy

Techniques of therapy are purely semantic, involving a communicative exchange of meaningful information. Treatment procedures are limited to conversations of various types, and there is a limit to what a therapist and patient can do with any purely semantic technique. These limitations are not by the nature of the therapist-patient relations, by what can take place in talking and listening, and by the topics chosen to be talked about. The relation between therapist and patient represents a working collaboration guided by a contract with stated and implied terms, usually involving payment of a fee for the therapist's services. Although the relation becomes intimate and emotionally arousing, it remains extremely one-sided, with the patient doing most of the talking. Disclosure is exchanged for confidentiality and neutral interest. The therapist's skills in listening and talking involve a general attitude of benevolent acceptance and specific acts of eliciting, focusing, clarifying, reflecting, and interpreting those relevant topics initiated by the patient. Criteria of relevance vary somewhat among therapy schools, but again there are limitations imposed by the regularities of deep human concerns—e.g., relations to significant other persons and the self to the self—and by what can in fact be said about them by therapists.

There exists a difficulty between and within schools of therapy in examining the facts of therapeutic conversation. When discussing therapeutic approaches, each school uses its own notions and language. But it is an open secret among cognate schools that this talking about therapy is highly unrelated to the talking that takes place in therapy. Official discussions about therapy tend to call up school allegiances and personal commitments. With an increasing use of tape recordings, movies, and television, we are in a position to observe what

therapists actually do rather than relying on what they say they do.

As already emphasized, theories regarding processes of mental change are not as developed as theories of mental distress. Every therapy school could use a theoretically justified set of principles for achieving change. The technical rules and principles currently used have come from long clinical experience and common-sense knowledge about human behavior. As an example of the latter, if you want a person to tell you about his inner painful thoughts, do not frighten him. This simple but effective principle is used by all schools. In its skillful applications, a therapist must be able to accept and control himself when stirred by feelings that can lead one person to attempt to frighten another.

Most of the rules for conducting therapeutic conversations are of this simple type. Some schools try to justify their techniques by appealing to fanciful metatheories or to animal experiments having no relevance to human behavior. But thus far technical rules are entirely empirical and justified only by clinical experience. This does not mean they are all wrong or can be easily dismissed, but because they lack a theoretical basis, it is difficult to sort out which techniques are truly effective and which can be dispensed with. For the time being, then, techniques must be learned through the oral tradition of apprenticeships in which empirical knowledge is passed on from the more experienced to the less experienced in the course of studying representative examples of clinical problems. And like the skills of all practical arts, they are performed by some people better than by others.

Until theories of change are worked out, a therapist must rely, in his practice, on simple rules and on a tacit knowledge that comes with clinical experience. The type of guides he needs most are technical rules that tell him what to say and when and how to say it in order to achieve his short range and long range goals. It is important to distinguish techniques from goals. Much of the therapy literature is clear about goals, although when the language refers to may be obscured (observationally), but it remains quite opaque as to how these ends are to be achieved technically. When one discusses the details of the therapist's utterances, all therapists say much the same things. And the utterances to which a patient responds are not the theory of the therapist's school. It is also true that statements about goals often refer to the end the patient should be rather than to what a therapist should do to help him become this way.

It is easy enough to state a goal of therapy in

problems and patients, making outcome comparisons across schools worthless.

When a practical art tries to improve its methods, it often turns to science for help. Psychotherapy, relying purely on semantic techniques, turns to the behavioral sciences of psychology, sociology, ethology, etc. As yet there has been no great help for the therapist from these areas, but the hope is that scientific research can contribute to a therapist's knowledge in order to make therapy more effective.

Research

A historical example of mutually benefiting relations between science and practical art can be found in Louis Pasteur's contribution to wine making. Although the process of fermentation was not well understood, wine had been made for thousands of years, and the results had been unpredictable. At the request of wine makers, Pasteur undertook a systematic study of the process of fermentation and discovered the role of bacteria. With this understanding it became possible to control fermentation by regulating the activity of bacteria. Nowadays the making of a great wine still requires intuitive art, but the making of a predictably sound wine is rather straightforward.

Like a wine maker, a psychotherapist follows a set of rules for achieving his goal—the relief of mental distress. As mentioned, these rules come from a body of clinical knowledge accumulated through the empirical experience of thousands of practitioners over many years. Why does a therapist believe in these rules when so few (if any) of them rely on scientific knowledge? One must here consider the nature of scientific, clinical, and common-sense knowledge. Scientific knowledge consists of reliable data and tested and confirmed (i.e., not disproved) hypotheses. Depending heavily on measurement and replication, it is precise and highly plausible in the face of the evidence. But it is also limited, lacking in scope and full of errors as history has demonstrated. Clinical knowledge stems from the slow accumulation of data and rough conceptions deriving from the astute observations and powerful intuition of generations of practitioners. Consensus develops through trial and error, and clinicians gradually come to agreement about the suitability of a technique. Common-sense knowledge consists of everyday observations and inferences at a low degree of refinement; it is often fallible and dubitable, but since it is not entirely unevaluated knowledge, it is indispensable. Refined common-sense knowledge becomes scientific knowledge, which then becomes part of common sense

again. If we had no scientific or clinical knowledge, we would still be able to manage human affairs about as well as we do today, using only common-sense knowledge of human behavior. A person has powerful aids of introspection and empathy in thinking and feeling about the behavior of other persons.

Scientific research in the problems of therapy should be able to cast light on some of the difficulties in the art. Ideally, one would like to have explanations of everything regarding mental distress and its relief. But this is not likely, nor is it even necessary for the art to improve. Not everything in therapy is a major problem. Only certain aspects merit a scientific study, and only certain questions deserve the labor required to attain a satisfactory answer.

Is psychotherapy effective? A useful and apparently simple question to ask and answer would be, "Is psychotherapy effective?" This has turned out to be such a difficult question for research to answer that we now must consider the question unanswerable when posed in this form. Thousands of therapists by now have treated millions of patients. Some patients report they are better, a few that they are worse, and some say they are the same. Therapists believe they help a majority of their patients. Therapists continue to be trained and to practice, and patients continue to seek therapy. There seems to be no widespread doubt that therapy is helpful, or at least that it is in some cases. But there is no satisfactory statistical evidence as yet that therapy benefits a population of patients. Are all these people, therapists and patients, unwittingly deceiving themselves and one another?

The issue is reduced to statistical evidence versus clinical knowledge with its elements of common sense. The failure of statistical evidence to demonstrate a phenomenon may reflect the weaknesses in our current tools of demonstration. Also a failure to reject the null hypothesis (which is what statistics attempts) does not establish the null hypothesis. On the other hand, therapists should realize better than anyone the weaknesses and uncertainty of clinical and common-sense knowledge.

The question of therapy effectiveness should be rephrased, because what the terms "therapy" and "effectiveness" refer to has never been operationally explicit. On the one hand, the term "therapy" does not refer to a homogeneous set of events. Unless the therapy can be observed by others, there is no guarantee that a therapist is doing what he should be doing and no estimate of how competently he is doing it. On the other hand, the term

"effectiveness" also initiates a snarl, because patients enter therapy with varying severity of mental distress and what is judged improvement for one patient may not be judged improvement for another. Furthermore, therapeutic goals contain values about desirable behavior, and unless judges share similar value systems, it is impossible for them to agree on whether the result of therapy was good or right.

Certainly every therapist has had at least one experience in which the outcome was judged favorable by himself, other clinicians, the patient, and others who know the patient. Such an experience carries the high conviction that therapy can benefit individual cases, and if it can happen to one patient, it should be able to happen to others. But to how many others in a population and what population? And perhaps it would have happened anyway "spontaneously." There is often mention of spontaneous remission in the literature, but as yet no one has presented any evidence that such a phenomenon exists.

Candid therapists admit they do not benefit all patients and wish that those who are helped could be helped more. The issue of effectiveness remains unsettled, but therapists are convinced that therapy has the potential to relieve mental distress. What is really needed is an improvement in methods to make therapy not only more powerful but more efficient.

Resistance and transference. If research is to help a practical art, it should address itself to crucial difficulties in that art. A crucial difficulty in all therapy involves a process known as "resistance." This term was derived from nineteenth-century electrodynamics, whose terms Freud used metaphorically in conceptualizing mental processes in terms of a flow of current through a circuit. The term refers to those hindrances a patient presents to explorations, scrutiny, and change. Clinical theory explains this phenomenon on the ground that a patient, although suffering distress, has achieved a mental state that is almost tolerable in many respects. Because the patient views any change in this state as a threat of even greater suffering, attempts to change are warded off and the state is defended for a long time. It is this fear of change and of being hurt that therapists believe to be a major factor in limiting the efficiency and effectiveness of therapy. Greater knowledge is needed about this process and its relation to "transference," i.e., the feelings and beliefs a patient develops about his therapist. Technical rules for dealing with transference and resistance may still be simple, but they should be based on a greater

understanding of what we are dealing with. Animal ethology and experimental psychology has already begun to indicate much about social bonds and social influence, especially between adults and their offspring (Scott 1962).

The future

Most research in therapy thus far has concentrated on the therapy situation itself, studying it directly as it exists in nature or studying experimental analogues. Naturalistic attempts to find common denominators among therapeutic approaches have not led us very far, because the comparisons have been too superficial and experimental attempts to duplicate the therapy situation have not brought about anything new. All this is ordinary research clearing up aspects of existing paradigms (Colby 1964). Sooner or later a new paradigm will appear, and extraordinary research will begin using surprisingly different presuppositions and suppositions. It is between the crevices of a *Menschanschauung* that new paradigms are discovered.

One attempts to forecast the future by extrapolating present trends and by predicting those discoveries or inventions needed to fulfill human wishes. The main trend in the profession of psychotherapy presently concerns the development of a therapist who is not a medical practitioner. With the admission that current training systems cannot meet the increasing social demand, a new type of therapist will emerge trained in the best way that can be agreed upon by psychiatry, clinical psychology, and social work. All kinds of impediments will be raised by organization officials, but the need is clear and reasonable men will eventually yield to it.

The second forecast involves discoveries and inventions needed by therapists who wish to improve their methods. The need for a theory of mental change has already been emphasized. This will be a fresh theory, not an amalgamation of current theories. For years there has been a demand for some sort of *rapprochement* between learning theory and psychoanalytic theory. A satisfactory combination seems unlikely as long as learning theory does not concern itself with such higher mental processes as symbol manipulation or with the fact that people think, talk meaningfully, and have awareness. Also, unless psychoanalytic theory develops novel concepts, no further contributions can be expected from it. The sorts of discoveries needed are those that can be provided by basic behavioral science or by a genius in the field of clinical observations and inference. Psycho-

therapy, as we know it now, will change markedly if vigorously and boldly worked on.

The inventions needed are recording apparatuses providing rapid information retrieval, voice-recognition devices, automated analyses of natural language, and computerized training devices for the learning of therapy. There is also the interesting question of whether a future computer might do as well, if not better, than a person in providing individualized therapeutic conversation for certain classes of problems (Colby et al. 1966). If a computer will be able to treat with semantic techniques thousands of patients an hour, this would be one answer to the problems of (a) the countable hundreds of thousands of hospitalized patients who never have an opportunity to talk with a therapist and (b) the uncounted millions of patients who could benefit prophylactically or remedially from therapeutic conversation.

CLIENT-CENTERED COUNSELING

Client-centered counseling and psychotherapy as a distinctive point of view and as a radical departure from current practices can be dated rather precisely to December 1940, when Carl R. Rogers, its leading exponent, presented a paper at the University of Minnesota on the attitude and orienta-

tion of the counselor. The paper later became the second chapter of his controversial book, *Counseling and Psychotherapy* (1942). The controversy engendered by this book centered as much upon what the counselor or psychotherapist was *not* to do in the psychotherapeutic situation as upon what he *was* to do. According to Rogers, he was not to guide or to reassure or support; he was not to interpret and was not to use an entire armamentarium of what were labeled "directive" standard techniques. Psychotherapeutic interventions, particularly interpretive explanations, were categorized as dangerous. It was recommended instead that the therapist stress what were called nondirective techniques, responding directly to the present, expressed attitudes of the client (reflection of feeling), and that the therapist convey his unequivocal respect for and acceptance of the client as he presented himself in the immediate present.

Rogers postulated that when the therapist demonstrates acceptance and permissiveness and shows understanding of the client's expressed attitudes and feelings, a process of personal change in the client would occur, in which the following stages could be observed: release of expression, achievement of insight, and development of capacities for making choices and of acting on the choices made. The main task of the therapist was to allow the stages to evolve, to facilitate a natural and inherent sequence, not to set the sequence into motion. Rogers also recognized that the therapist had his own propensities to become emotionally involved with his client in ways which resulted in directiveness and that, therefore, the therapist should work at circumscribing these propensities in himself. He stressed the complete abdication of power in the therapeutic relationship, in contrast with current and standard techniques, in a manner which seemed to many to strike directly at the heart of the current practice of psychotherapy in medicine, in social work, in nonmedical settings, and in vocational psychology as well. Pained and angry responses from the ranks of these helping professions were immediate, intense, and long-sustained.

Personal change in psychotherapy

Counseling and Psychotherapy was almost entirely theory-free and empirical in tone, and intentionally so. In 1942, Rogers was a clinical professor formulating his clinical experience for the benefit of clinical students; like many clinicians he was somewhat scornful of current psychological theories, regarding them as sparse and simplistic compared with the richness and complexity of the

clients with whom he worked. The storm of controversy ensuing upon the publication of *Counseling and Psychotherapy* stimulated a flow of research and theoretical development by Rogers, his associates, and their students which has not yet abated. The development of theory and research in all areas until approximately 1956 was summarized and integrated by Rogers (1959, pp. 184-252). The approach to understanding personality, psychotherapy, and interpersonal relationships is entirely phenomenological. Technique is minimized and the necessary and sufficient conditions for inducing psychotherapeutic personality change are stated to be the following:

1. Client and therapist are in contact.
2. The client is in a state of incongruence: there is a discrepancy between his perceived self and his actual experience. He is vulnerable or anxious.
3. The therapist is congruent in the relationship with his client: his perceptions of this relationship are accurate symbolizations of the actual experience.
4. The therapist is experiencing unconditional favorable regard toward his client.
5. The therapist is experiencing an empathic understanding of the client's internal frame of reference.
6. The client perceives, at least to a minimal degree, the unconditional favorable regard of the therapist for him as well as the empathic understanding of the therapist.

It is noticeable that no techniques and no behavior prescriptions appear in this account. Everything is couched in terms of the experience of the client and of the therapist. Nonetheless, most responses of client-centered therapists continue to be reflections of feeling based on their perception of the internal frame of reference of the client. The behavior of client-centered therapists follows from this premise: The probability that the client will perceive the therapist as prizing (positively valuing) and understanding him is maximized when the therapist manages to convey his prizing attitude of unconditional favorable regard and when the therapist communicates his empathic understanding to the client in a consistent way.

Basic concepts. The theory of personality presented is also phenomenological and shows the influence of gestalt theory. The only motive postulated in the theoretical system is the actualizing tendency; the inherent tendency of the organism to develop all of its capacities in ways serving to maintain or enhance the organism. The actualizing tendency reflects in large part the tendency to develop autonomy and to lessen heteronomy, or

control by external forces. The actualizing tendency is a property of the total organism.

The self concept is the consistent conceptual gestalt (organization) derived from the perceptions of the "I" or the "me" that are developed in interaction with significant others. The ideal self concept denotes the self concept to which the individual aspires. The self-actualizing tendency is a subsystem of the basic organismic actualizing tendency and is a consequence of the development of the self concept. Self-actualization is the actualization of that portion of the experience of the organism which is symbolized in the self concept. When self-experience and the remainder of the experience of the organism are congruent, then the actualizing tendency remains relatively unified. If self concept and experience are incongruent, then self-actualization and actualization tendencies are incongruent. In this case, the individual is maladjusted; his self concept reflects a conflict between self-actualizing motives and actualizing motives. [See SELF CONCEPT.]

The self concept does not direct the organism; indeed, the self concept derives from the actualizing tendency and is but one aspect of the tendency of the organism to react and behave so as to maintain and enhance itself. Motives or needs such as the need for favorable recognition from others and the need for self-esteem arise out of the organism's experiences in relation to interpersonal transactions and their vicissitudes. In a broad sense, "experience," in Rogers' view, is the organism's receiving the impact of sensory or physiological events happening at the moment; experience is what happens to the organism, including what happens within it. However, in a more restricted meaning "to experience" for Rogers also denotes the accurate symbolization in awareness of the sensory or physiological events.

The theory presented by Rogers, although containing many propositions, is basically simple. It concerns the development and self-development of the organism, the accurate symbolization in awareness of experience, and the perception of threat, with consequent defenses and effects upon interpersonal behavior. The development of an accurate self concept is held to be a basic capacity of the organism.

An inaccurately symbolized self concept emerges because the individual, in the course of development, begins to have a need for favorable regard from others and an analogous and consequent need for favorable self-regard but perceives himself as being only conditionally prized or loved by others. He incorporates this conditional prizing into his

self concept and subsequently evaluates experiences on the basis of conditional prizings instead of in terms of the basic actualizing tendency. Perception of unconditional prizing by others leads, on the other hand, to satisfaction of the needs for favorable regard and self-regard in a way that is congruent with the basic actualization tendency. Development under optimal conditions of unconditional prizing leads to a person who is fully functioning, open to experience, and psychologically adjusted.

Some comments on the theory are in order. As stated before, it is relatively simple, having neither the comprehensiveness, say, of psychoanalytic theory nor the seemingly rigorous and elegant simplicity of behavior theory. Not too much is said about motivation, and the defense mechanisms, such as repression, denial, and reaction formation, are taken for granted: they have been discussed and investigated elsewhere. The theory was developed to account for what other theories neglected and to stress a view of human nature and experience not currently dominant in Western culture, namely, that the individual inherently actualizes and self-actualizes, is personal and subjective, is not at the mercy of individual drives, and has inherent capacities for realistic adaptation and unrestricted experiencing. He is often conditionally valued by significant others early in life and often responds by evaluating his self in terms of these conditional prizings. The individual has a history that results in various degrees of congruence between the actualization and the self-actualization tendencies: the lower degrees of congruence are maladjustive; the higher degrees approximate the fully functioning, fully experiencing individual, who evaluates autonomously and is personally creative. [See DEFENSE MECHANISMS.]

Clinical and empirical foundations. Despite its phenomenological language, Rogers' theory has the virtue of being close to and being derived from clinical observation. When the client is in the psychotherapeutic situation, when he is unconditionally prized and is well understood by the therapist as he presents himself, he does change his self concepts, he does react more openly, he does abandon maladaptive strategies, maneuvers, and symptoms in relation to the therapist. He usually does not develop a "transference neurosis," and his expressive style changes. The organization and use of language changes, and the individual comes to act differently with others than before. Observations of such changes led to the theory. What is not observationally based is the theoretical prediction of the increase in congruence between self concepts and experience. What is observed is that self con-

cepts change and that the individual expresses himself as being in some ways more like the person he wants to be. However, the congruence of self concept and ideal concept is suspect because it is observed that some individuals claim to have congruent selves and ideals when obviously such is not the case; i.e., interpersonal behavior is not consistent with the claim, and worse, other persons, such as paranoid individuals, seem to have congruent self concepts and ideal concepts but are clearly psychologically maladjusted; thus the recourse by Rogers to the discrepancy between self concept and experience and between self-actualization and the actualization tendency, even though such discrepancies are not actually observed in the psychotherapeutic interaction.

In general, theoretical statements by writers within the client-centered orientation, with the exception perhaps of Raimy (1943) and Snygg and Combs (1949), have the same clinical-empirical and action-oriented flavor as those of Rogers. Complex behavior is considered. Little attempt is made to provide careful definitions in the sense in which terms such as stimulus, response, drive, and response generalization are carefully defined in, say, behavior theory because the primary referents can be pointed to in recordings, motion pictures, etc. This discriminability of primary referents is conceived to be an advantage. Considerable difficulty has been encountered by behavior theorists in defining such terms as stimulus, response, and response generalization unambiguously even for simple situations, and when they are applied as behavior therapy, the specification of reinforcing stimuli and of response generalization has been so vague that it seems safe to say that for some of the better-known studies it would be easy to obtain quite different results using the same reinforcing stimuli described by the investigators.

The therapy process. Rogers' specifications of the necessary and sufficient conditions of personality change in psychotherapy are to a large extent understood by client-centered therapists in terms of the predominant conduct of therapists: unconditional prizing behavior, mostly expressed nonverbally, and reflections of feeling as communications of manifest themes that occurred in the client's communications. The communicative behavior of clients includes the nonverbal, gestural, expressive components of communication which are linguistic in nature and which serve to modify the meaning of symbols and signs.

What happens in the psychotherapeutic hour when the therapist conducts himself in the manner mentioned above? Numerous studies, most of

them cited by Rogers (1959), have been addressed to this question. While these studies are satisfactory in a certain sense, they do not really describe the events at all well. Hence, a naturalistic description will be attempted. The communicative behavior of the client usually, in contrast with psychotherapies in which the psychotherapist's responses are interventive, shows thematic unity. Thematic unity is also evident in the sequence of responses. Along with this, the voice qualities change, and language usage also changes in such a way that the client appears to be more expressive and integrated in his communicative behavior, to be using a richer and more figurative language. When the therapist accurately symbolizes the themes in a client response, he is in actuality amplifying and developing them through his own language and voice qualities. Often these responses of the therapist are met by the client with "Yes, yes," "That's it exactly," or "Exactly," spoken with considerable emphasis. The theme voiced by the therapist (but voiced by the client immediately before) is then elaborated and developed with considerably more differentiation in both language and voice, creating an impression of supple and spontaneous flexibility. This is true even for quite disturbed clients communicating initially in a passive way and with the passive voice, and using such phrases as "This comes to mind." As the therapist's language becomes richer and more apt, as he makes more use of his voice, as his expressive gestures become more explicit, the more thematic is the development, the more figurative is the speech, and the more closely knit, congruent, and spontaneous become the interchanges of the client and the therapist. This behavioral process, so difficult to describe but so denotable in audio and photographic reproductions of psychotherapy interviews, at its best has the kind of literary quality one might ascribe to recitations of the ancient Greek bards, whose recitations were worked out anew in each encounter with an audience. Published reports of client-centered therapy are, unfortunately, poor representations of the process described.

Later theoretical development

Theory development since 1956 has largely concentrated upon developing the phenomenological perspective (Shlien 1962), with much stress on the experiencing process in relation to personality change (Gendlin 1964). Gendlin (1962) has written a philosophical treatise on personal experiencing that stresses the relation of experiencing to the creation of meaning. This work developed out of his training as a philosopher and his extensive en-

counters with client-centered psychotherapy. In extending his concept of experiencing to the understanding of concepts and values (1963; 1964), psychotherapy (1961), and personality change (1964), Gendlin has concluded that changes may occur in psychotherapy even before concepts have been attained that accurately represent feelings referred to by the client. This occurs because the therapist's responses themselves may lead to symbolic completions, closures, and elaborated themata even when the client does not perceive the therapist as prizefully understanding. In emphasizing the influence of the therapist in promoting closure, Gendlin is in effect changing Rogers' conditions for personality change.

Dissatisfied with the postulational character of the actualization tendency, Butler and Rice (1963) have proposed that adient motivation, the need for experience, is the primitive base for the actualization and self-actualization tendencies. On the basis of studies of preference for complexity or novelty, of stimulus deprivation and of neurophysiological processes, they propose that adience is rewarded by thinking processes as well as by environmental transactions. The self-actualizing, fully functioning person autonomously creates experience for himself, and he can autonomously reinforce and extinguish behavior (learn) without moving a muscle. [See STIMULATION DRIVES.]

With respect to psychotherapy, Butler and Rice maintain that a stimulating, expressive communicative style on the part of the psychotherapist enriches the experience of the client, focuses associations by reflections of feeling, and leads to symbolic completions and thema development. A "difficult" client with a poor prognosis may lower the responsive participation of the therapist, thus creating an experientially impoverished environment matching his inner experiencing, with the consequence that enrichment of experience may not ensue. Clients with poor prognosis are just those who, in the therapeutic interaction, are likely to create the conditions leading to lack of progress and no constructive personality change. Butler and Rice maintain that the therapist who can sustain a participative, stimulating, and responsive expressive style is likely to induce progress in therapy even when such progress seems improbable. Evidence supporting their hypotheses has been presented by Wagstaff (see Butler et al. 1963) and Rice (1965.)

Research

Research on client-centered psychotherapy has been summarized or cited extensively in Rogers (1959; 1960), Seeman (1956; 1965), Butler

(1958), and Grummon (1965). Attention here will be centered on the proposition that the changes noted in psychotherapy are due to the psychotherapeutic encounter rather than to spontaneous remission or other extrapsychotherapeutic agents. All work cited has been discussed in Rogers (1959), except when cited by year.

Early studies tended to be confined to content analyses of transcripts of therapy interviews. These studies showed that, to a considerable extent, therapists did, indeed, consistently employ the techniques they claimed to use (Porter, Snyder, Seeman, Strom). Furthermore, for clients it was demonstrated that there was a change in the proportion of responses indicating insight, self-exploration, and integration (Porter, Snyder, Curran, Stock, Hoffman); that there were decreasing proportions of distress and discomfort responses and increasing proportions of favorable responses to self (Raimy, Assum, & Levy; Kauffman & Raimy; Zimmerman); that decreasing self-exploration was exhibited when therapists complied with requests for guidance, information, and support (Bergman 1951); that there occurred an increasing acceptance of self and others (Sheerer); and that there was an increased correspondence between ideal self and self concept for cases evaluated as successful, whereas this did not occur in cases evaluated as unsuccessful (Aidman 1951; Bowman 1951).

In later studies, control techniques and measuring devices suggested by theory and research results were employed. Self-ideal relations were found to increase during the course of psychotherapy for the client group as a whole, the increase being greater for the group of clients judged to be definitely improved in terms of both therapist ratings and Thematic Apperception Test (TAT) ratings (Butler & Haigh 1954). The therapist's judgments were made independently of the TAT ratings and of the tested self-ideal relations. There was a significant increase in the variability of the self-ideal correlations at the end of therapy and at the end of a follow-up period, indicating that self-acceptance was decreasing for some clients and increasing for others. The majority of the changes reflected increasingly self-ideal correspondence, however.

Butler showed that 11 of the clients serving as their own controls, to whom tests were administered 60 days prior to therapy, immediately before therapy, and 60 days or less after therapy began, changed their self-descriptions significantly more during the in-therapy period than during the no-therapy period (Butler 1964a).

Another control feature is the rating of clients

on a scale measuring maturity of behavior (Rogers 1954). Friends of the clients who were not informed that the clients were in therapy and who knew nothing of the research, made these ratings. In general, mean ratings on these scores did not change significantly between pretherapy, therapy termination, and follow-up testing. However, when the clients were stratified on the basis of therapist rating on a nine-point scale of success, the mean increase on maturity scores from pretherapy to therapy termination was statistically significant for clients whose ratings were in the 7-9 range, while there was a statistically insignificant decrease for clients rated in the 1-5 range. For the period between pretherapy and follow-up testings there was a significant increase in average maturity ratings for clients in the 7-9 range and a significant decrease in average maturity ratings for clients in the 1-5 range.

The findings are remarkable because the groups used were very small and the therapist rated clients solely on the basis of interview behavior, while the lay observers presumably did not know their friends were in psychotherapy and knew nothing of the research. Comparable ratings on normal controls showed no mean change in score between testing periods.

In a later study of many of the same clients, Butler (1964b) related self-reports, ratings by independent lay observers, and ratings by therapists. His results indicate that the vantage points of clients, therapists, and observers provide similar information, although the judgments are made on different bases.

While this particular group was small, cross validation with another group yielded the same conclusion about the effects of psychotherapy on self-description. Cartwright and Vogel (1960) reported on a group of clients for whom they individually matched periods of waiting for therapy with in-therapy testing points. The wait periods varied from 4 to 24 weeks. They found statistically significant differences in the variability of self-descriptions indicative of adjustment (highly related to self-ideal correspondence) during the treatment period over and above those obtaining in the waiting period. Psychotherapy was held to account for the increase in the variability of self-description scores.

In another study reported by Butler (1964a), the self-ideal correlations of clients with good and poor prognoses were compared with those of clients with good and poor prognoses who were not receiving psychotherapy. The treatment group received ten weeks or less of psychotherapy, whereas the control group received no psychotherapy for a ten-week period. Analysis of covariance of the self-

ideal correlations revealed that those of the treatment group changed more than those of the no-treatment control group and that the majority of the changes were in the direction of increased correspondence of self concepts and ideal concepts.

When clients are matched on prognosis and are randomly assigned, one can infer from these findings that self-acceptance does change in, and as a result of, client-centered psychotherapy. One can also infer that changes in self-acceptance are related in some way, not necessarily linearly, to changes in maturity of interpersonal behavior as seen by lay observers, to psychodynamic changes as reflected in indexes derived from projective tests, and to changes in personal integration and level of adjustment as perceived by therapists. No single study provides perfect control, but the progressive character of the results and the relationships of the measures lend considerable weight to the hypothesis that self-acceptance changes as a result of client-centered psychotherapy and that other changes, particularly maturity of interpersonal behavior, are associated with self-acceptance and the process of psychotherapy.

A particularly interesting study was conducted by Bills (1950). After a 30-day control period in which none of 18 third-graders who were retarded readers received play therapy, eight received client-centered play therapy and ten received no treatment. An analysis of covariance showed a statistically significant difference in gain in reading score for the treated group compared with the untreated group. Bills's study bears on the question of what kinds of behavior are affected by psychotherapy, adding reading to the list of self-regarding behavior, interpersonal behavior, and projective behavior. [See READING DISABILITIES.]

Research in client-centered psychotherapy since Rogers completed his survey (1959) has centered largely upon the conditions of psychotherapy as provided by the psychotherapist and upon therapist characteristics. Wagstaff has found three factors of expressive style in client verbal behavior, two of which are related to various criteria of outcome of psychotherapy (Butler et al. 1962; 1963); and Rice, analyzing responses of the therapists of the clients studied by Wagstaff, has found three factors of therapist vocal and lexical style, two of which are also related to various outcome criteria (1965). These studies support the hypothesis of Butler and Rice, alluded to earlier, that clients with poor prognoses deleteriously affect the responsiveness of their therapists.

Duncan (1965), studying a variety of discrete paralinguistic behaviors in both client and therapist, found significant relationships, on the one

hand, between one aspect of therapy "process" (patterns of voice quality) and the therapist's judgments of the process, and, on the other hand, between this process and client test performance both before therapy and after 20 interviews.

Gaylin (1965) devised a Rorschach function score designed to measure psychological health. Obtaining this score for pretherapy and post-twentieth-interview Rorschachs, he found that those clients with high ratings of improvement by their therapists exhibited improved scores; those with low ratings, poorer scores. Gaylin's function score also correlated significantly with paralinguistic factors studied by Duncan.

Truax and Carkhuff (1963), working with Rogers, have presented evidence to show that when therapists dealing with hospitalized patients provided high levels of warmth, empathy, and congruence, patients improved; when they did not, patients became worse.

Client-centered psychotherapists hypothesize that the person is motivated largely by actualizing and self-actualizing tendencies which result in favorable personality change under proper interpersonal conditions initiated by the therapist. The results of studies of the psychotherapeutic situation and its effects strongly support these hypotheses. These studies also show that changes observed in psychotherapy are reflected in interpersonal relationships and in favorable and enduring changes in the structure of self concepts. In addition, the techniques and qualities of client-centered therapists significantly affect performances in other types of situations.

Although there are a few studies suggesting that client-centered psychotherapy compares favorably with other approaches (e.g., Shlien et al. 1962), it would be premature to claim that client-centered psychotherapy is more efficacious than other psychotherapies. This is due in part to the lack of systematic research on personal change in psychotherapy. Furthermore, different approaches to psychotherapeutic treatment, such as behavior therapy, apparently have goals somewhat different from those stated for client-centered psychotherapy. These circumstances render systematic comparisons difficult, if not impossible, at the present stage of development of research on psychotherapy. Currently, an opinion on the relative efficacy of various forms of psychotherapy must be regarded as just that and no more.

GROUP PSYCHOTHERAPY

Group psychotherapies are based on the recognition that, with proper guidance, certain types of persons with psychiatric disorders can help each other. In all forms of group therapy, patients and a therapist repeatedly meet to conduct certain activities within the framework of a special group structure and code. Their emotionally charged interactions with the leader and with each other may help to correct their faulty communication behavior and their distorted perceptions of themselves and others, leading to improved social and personal functioning and to relief of psychic distress.

Group healing methods are as old as individual ones. From earliest times, sufferers have sought relief through group activities at religious shrines, and many continue to do so. Group therapies began to emerge as recognized and legitimate forms of psychotherapy, however, only in the 1920s.

Many early practitioners exploited the instructional and inspirational potentialities of groups in a purely empirical way; but two pioneers, Trigant Burrow and J. L. Moreno, offered theoretical rationales that, although not in the mainstream of psychiatric thought, had considerable influence. According to Burrow (Riese & Syz 1963), mental disorder was a disturbance in communication, created largely by a person's "privately cherished and secretly guarded" image of himself; the aim of group therapy was to enable him to express himself as he really was by exposing the socially determined basis of his self-image. Moreno (1959) stressed the freeing of spontaneity through encouraging the patient to act out his problems, with the aid of other patients as well as of therapists, in the presence of a vicariously participating audience. In the 1930s psychoanalysts began to experiment with group therapy based on psychoanalytic theory. During World War II, psychotherapists in the armed forces were forced to resort to group methods to handle the enormous load of patients. These methods proved so successful that they spread with almost explosive rapidity. Many modifications were introduced and applied to an ever increasing variety of psychiatric conditions in many different settings. By the 1950s, group therapy in the United States had assumed the dimensions of a movement and had two professional associations, each with a journal devoted to promulgating it.

The wide popularity of group therapies may be partly due to the fact that they offer a type of intimacy characteristic of the family and other primary groups. The urbanization and mobility of modern life have reduced opportunities for such relationships, and the shallow, transient, competitive sociability of residential development, office, and club is not an adequate substitute.

Characteristics of group therapy

Therapeutic groups are conducted in outpatient clinics, private offices, social agencies, mental hospitals, and correctional institutions. Leaders are characteristically psychiatrists, psychologists, psychiatric social workers, or ministers. Some groups are conducted by their own members, without professional guidance. Most forms have a single leader, often with an observer to record what occurs; but some have cotherapists—usually a man and a woman—who try to take different functional roles, such as "father" and "mother."

Composition of therapy groups. Most therapy groups consist of from 7 to 25 strangers selected according to a principle such as age, institutional

residence, or diagnostic category. Examples are groups composed of children, adolescents, mature adults, or the aged; of alcoholics, psychotics, or neurotics; or of persons whose only common feature is residence in the same mental hospital or correctional institution.

Increasing efforts are being made to group patients within these broad categories in such a way as to maximize their communication potential. It has been noted that groups tend to elicit certain group roles in predisposed members. For example, one repeatedly finds monopolists, nonparticipants, therapist's assistants, members who try to hold the stage by constantly complaining, and others who try to dominate by moralizing (Rosenthal et al. 1954). This raises the possibility of balancing groups by selecting prospective members with regard to their predilections for different group roles. Observation of patients' actual group behavior seems to be a more reliable way of determining this than individual interviews and psychological tests. To this end, assignment of patients to therapeutic groups may be based on their behavior in a diagnostic group, to which all patients are briefly assigned, where this is administratively possible.

A recent trend toward treatment of family groups as a unit is based on the view that the member officially labeled the patient is in reality the victim of a disturbed communication network in which other family members are also involved (Bell 1961; Satir 1964). This approach seems especially promising when the patient is chronologically or psychologically immature, as in the case of a child, an adolescent, or a schizophrenic.

Therapists meet privately with patients before the first group meeting to determine their suitability for inclusion and to prepare them for the group; they meet again, later, to evaluate the patients' readiness for discharge. The extent of private patient-therapist contacts at these and other times varies widely, depending on the therapist's conceptualization of treatment; but it is generally agreed that such meetings must be limited if they are not to drain important material from the group sessions.

This limitation also holds for meetings of patients between formal sessions, since such informal meetings create opportunities for antitherapeutic as well as therapeutic encounters. With family groups and married couples, such meetings are of course unavoidable; and they seldom can be completely prevented in groups of strangers. Extra group meetings foster growth of group cohesiveness and give members opportunities to interact away from the inhibiting presence of the therapist,

which may be advantageous. On the other hand by diminishing the members' "social incognito" they may inhibit candid expression of feeling in the group and may foster "acting-out" of personal problems through, for example, exploitative or anxiety-relieving sexual behavior, thereby removing the problems from the helpful scrutiny of the group. Some therapists deal with this problem by prescribing meetings in their absence, so that these become part of treatment; all try to set the ground rule that there be no secrets from the group. The knowledge that anything occurring in an extra-group encounter may be reported to the group usually has an inhibitory effect on antitherapeutic activities.

Leader-centeredness or group-centeredness. Methods of group therapy can be ordered with reference to their degree of leader-centeredness or group-centeredness. Since group members are chosen by the therapist and initially expect help only from him, all groups begin as leader-centered. Throughout the duration of some groups the therapist continues to be seen as the sole therapeutic agent, and the group as merely the arena in which members interact with him and each other. Group centered approaches attribute considerable therapeutic effects to properties of the group itself. Some groups have no official leader. In others, the leader encourages patients to rely increasingly on each other and deliberately tries to foster a group code and group attributes, such as cohesiveness, that have therapeutic potential. Actually, in therapy groups as in all others, leader behavior, member behavior, and group processes continuously interact. For example, a controlled study of group therapy with hospitalized patients found that intrapersonal exploration by the patients was associated with certain aspects of the therapist's style of leadership and with certain properties of the group itself (Truax 1961).

Degree of activity structure. Groups can also be roughly classified in terms of the extent to which their activities are organized. Some, such as Alcoholics Anonymous, therapeutic social clubs and Recovery, Incorporated (Wechsler 1960), rely on tightly structured, prescribed activities; others often termed interview or free-interaction groups create an ambiguous situation and place responsibility for what occurs on the members. In general the more structured the group, the larger its size can be.

Free-interaction groups. To illustrate the range of group therapies, three divergent types may be briefly described. Free-interaction groups typically consist of up to eight adult outpatients and a pro-
